

## Math 300A Winter 2011

**DEFINITION:** Given two integers  $m$  and  $n$ , an integer  $k$  is a **common divisor of  $m$  and  $n$**  if  $k$  divides  $m$  and also  $k$  divides  $n$ . (In other words, there are integers  $a$  and  $b$  so that  $m = ka$  and  $n = kb$ .)

**DEFINITION:** The **greatest common divisor of  $m$  and  $n$**  is a positive integer  $d$  such that  $d$  is a common divisor of  $m$  and  $n$  and any other divisor  $k$  of  $m$  and  $n$  also divides  $k$ . **The greatest common divisor of  $m$  and  $n$  is denoted by  $\gcd(m,n)$ .**

**DEFINITION:** Two integers  $m$  and  $n$  are said to be **relatively prime** if their greatest common divisor is 1.

**Examples:** The  $\gcd(150, 45)$  is 15, since  $150 = 2 \cdot 3 \cdot 5 \cdot 5$  and  $45 = 3 \cdot 3 \cdot 5$ . The  $\gcd(49, 39) = 1$  since  $49 = 7 \cdot 7$  and  $39 = 3 \cdot 13$ .

## Assignment 9 (due Wednesday, 3/9)

**Problem 9-1:** Post at least one of these to the Piazza site.

- Submit the answer to a homework problem from a previous homework (no duplicates unless your answer is significantly different).
- Comment on another student's proof.
- Post a question whose answer you care about.
- Answer another student's question.

**Problem 9-2:** Prove this theorem that we have been using.

For any integers  $m$  and  $n$ , there is an integer  $q$  and an integer  $r$ , with  $0 \leq r < |m|$  so that  $n = qm + r$ .

Hint: Induction on  $n$ .

**Problem 9-3:** Prove: If  $m, n, q$ , and  $r$  are integers, then the set of common divisors of  $m$  and  $n$  is the same as the set of common divisors of  $m$  and  $r$ .

What does this mean if  $r = 0$ . Is the theorem still true?

Conclude as a corollary:  $\gcd(m,n) = \gcd(m,r)$ .

**Problem 9-4:** Use the result of 9-3 for an algorithm to find the  $\gcd$  of any two integers that does not require factoring them into prime factors.

Then use your algorithm on some non-obvious numbers, including some of at least 4 digits and preferably more.

**Hint 1:** The first step is  $n = qm + r$ , with  $\gcd(m,n) = \gcd(m,r)$ . The next step is  $m = q'r + r'$ . With  $\gcd(m,r) = \gcd(r,r')$ . Notice that the remainder is smaller at each step, so at some point it must be zero. What does this tell you when you get to that point?

**Hint 2:** Try out these steps (and continue them) with some simple examples, such as  $n = 150$  and  $m = 45$ .

**Problem 9-5:**

Any function  $X$  from  $\mathbb{N}$  to  $\mathbb{R}$  defines a sequence of real numbers,  $X_1, X_2, \dots$

The number  $A$  is defined to be the limit of  $X_n$  as  $n \rightarrow \infty$  if this is true:

For every  $\varepsilon > 0$ , there is a positive integer  $N$  so that for all  $n > N$ ,  $|X_n - A| < \varepsilon$ .

Notation:  $\lim_{n \rightarrow \infty} X_n = A$

**PROVE:** If  $X_n = \frac{2n-1}{n}$ , then  $\lim_{n \rightarrow \infty} X_n = 2$ .

**Problem 9-6:**

Suppose that  $Z_n$  is a sequence for which this is true: There is a positive integer  $N$  such that for every  $\varepsilon > 0$ , for all  $n > N$ ,  $|Z_n - A| < \varepsilon$ .

What would an example of such a  $Z_n$  be? What can you prove about  $Z_n$  that must be true.

**Problem 9-7:**

(a) Write what it means for a number  $A$  *not* to be the limit of  $X_n$  as  $n \rightarrow \infty$ . In other words, what is the negation of the definition in 9-5.

(b) If the sequence  $Y_n = (-1)^n$  for all positive integers  $n$ , prove that there is no number  $A$  that is the limit of  $Y_n$  as  $n \rightarrow \infty$ .
