Week 15 – Slide Rules

Before the (digital) calculator was invented, every mathematician, engineer, and scientist carried a *slide rule* in their pocket. A slide rule is a kind of mechanical calculator that works like a fancy ruler. Slides rules were used well into the 1960s and 1970s — their calculations were even precise enough to be trusted by NASA engineers putting men on the moon! Today, we'll take a look at this piece of mathematical history and what it can teach us.

1 Getting to know your slide rule

Your Math Circle instructors have kindly made you a slide rule to use! Here are what the parts of a slide rule are called.

- 1. The scales all sort of look like rulers, but something is weird about them. What is unusual about them?
- 2. Find the C scale and CI scale on the slider. How are they similar and different?
- 3. Move the hairline to 1.2 on the C scale. Read the numbers on the CI scale and the B scale as accurately as you can.

CI:	B:	
_		

2 Multiplication

Use your slide rule to follow along this tutorial.

To multiply 1.7×2.6 ,

- Align the left-hand 1 on the C scale with 1.7 on the D scale.
- Move the hairline to 2.6 on the C scale.
- Read the number on the D scale.
- 4. What number do you see? (Estimates are always fine, but be as accurate as possible.)
- 5. Use your slide rule to compute 3.8×2.1 .
- 6. Use your slide rule to compute 1.13×1.26 .
- 7. How could you use your slide rule to compute 17×330 ? Write down both your method and the answer.

8. How could you use your slide rule to compute 0.7×6 ? Write down both your method and the answer. (Hint: Look at the very right of your C scale. Why might that say 1, not 10?)

9.	Use	your	slide	rule	to	compute	289	X	812.
----	-----	------	-------	------	----	---------	-----	---	------

3 More features of your slide rule

10. One method to do division on your slide rule uses only the C and D scales that you've already been using. Figure out this method and write it down. (Hint: try to multiply $2 \times 3 = 6$. How can you compute that $6 \div 3 = 2$?) Then divide $113 \div 43$.

- 11. Another method to do division uses the CI scale and D scale. Using them to compute $a \div b$ is just like using the C and D scales to compute $a \times b$. That is,
 - Align one of the 1's on the CI scale with a on the D scale.
 - Move the hairline to b on the CI scale.
 - Read the number on the D scale, and adjust the decimal point if needed.

Use this method to divide $589 \div 2.6$.

- 12. Use your favorite method to divide $0.184 \div 23$.
- 13. The B scale of your slide rule, used with the C scale, can help you find the square of a number. That is, for any number a, it can help you find $a \times a$. Play around with the slide rule to figure out how to do this, and be sure to mention how to interpret the numbers on the right half of the B scale.

14. Recall that the square root of a number a, denoted \sqrt{a} , is the number which, when squared, gives you a. For example, $\sqrt{9} = 3$. How can you use your slide rule to compute $\sqrt{41}$? Write down both your method and the answer.

15. Try to do multiplication (and/or division) using the A and B scales, just as if they were the same as the C and D scales. Does it always work? If so, what are the advantages and disadvantages to using the A/B scales over the C/D scales for multiplication? If not, when will it not work?

4 Doing longer calculations

Try to do all of the following problems without writing down or memorizing any intermediate calculations. Hint: the hairline will be super helpful!

16.
$$2.8 \times 1.6 \times 7.3$$

17.
$$0.21 \div 54 \times 9.81$$

18.
$$45 \times \sqrt{70}$$

19.
$$3 \times \sqrt{\sqrt{5}}$$

20.
$$1.9 \times \sqrt{3.8 \div (8.4 \times 2.3)}$$

5 How does it work?

In order to really explain how a slide rule works, we need to first discuss an even more antiquated form of technology that came before it — the log table.

Recall that a^b means $\underbrace{a \times \cdots \times a}_{b \text{ times}}$. For example, $3^4 = 3 \times 3 \times 3 \times 3 = 81$.

21. Suppose a, b, and c are whole numbers. Why is it true that $a^b \times a^c = a^{b+c}$?

By using this fact, we can turn multiplication problems into addition problems! And although the basic definition of a^b only works when b is a whole number, it turns out that we can fill in the gaps to make the formula continue to work for decimals and fractions. People worked very hard to compute very accurate, giant tables to tell you for any given number a, if you wanted to write it as 10^b , what b should be. This is called a *table of logarithms*, and scientists used them for centuries before calculators were invented.

- 22. You know that $10^2 = 100$ and $10^3 = 1000$. Try to guess what number b makes $10^b = 500$.
- 23. In the table of logarithms provided for you in the back of this packet, find row 50, column 0, meaning 500. The number in the table is the first 4 digits after the decimal point of the number b. What is b? How close was your guess?

24. Using the log table, find the number b such that $10^b = 47$, and the number c such that $10^c = 673$.

b: c: _____

25.	Use the fact that $10^b \times 10^c = 10^{b+c}$, along	with your	answers to	the previous	question
	and your log table, to estimate the value of	47×673 .			

The first inventors of the slide rule relied on log tables to create their device.

26. Imagine an "addition slide rule" that just consists of two standard rulers. (Unfortunatly we don't have any to demonstrate, just try to imagine.) How can you use two rulers to add numbers, and why does that work?

27. Suppose you wanted to design a slide rule with just the C and D scales. Each scale should be 10 inches long, with the number 1 on both ends, as usual. You have a standard ruler and a log table. Where should you draw a mark for the number 2? Then, explain why this choice lets you use the C and D scales to multiply numbers.

28. What is the method used to label the CI scale? Use a fact similar to $a^b \times a^c = a^{b+c}$ to explain why this allows you to divide numbers, following the same process as multiplying on the C scale.

29. The A and B scales are constructed to be the square of the C and D scales. Based on this construction, explain why the left and right halves of the A and B scales ended up being exact copies of the C and D scales squished half as long. (And therefore, we can actually use the A and B scales to multiply and divide as well!)
