

Steady state and Transients

$$\ddot{y} + 0.2 \dot{y} + y = \cos 2t$$

$$\textcircled{1} \quad r^2 + 0.2r + 1 = 0$$

$$(r + 0.1)^2 = -0.99$$

$$r = -0.1 \pm i \sqrt{0.99}$$

$$y_H = C_1 e^{-0.1t} \cos(0.995t) + C_2 e^{-0.1t} \sin(0.995t)$$

$$\textcircled{2} \quad y_P = A \cos 2t + B \sin 2t$$

$$\dot{y}_P = -2A \sin 2t + 2B \cos 2t$$

$$\ddot{y}_P = -4A \cos 2t - 4B \sin 2t$$

$$\ddot{y}_P + 0.2 \dot{y}_P + y_P = (-3A + 0.4B) \cos 2t$$

$$+ (-3B - 0.4A) \sin 2t$$

$$\ddot{y}_p + 0.2 \dot{y}_p + 4y_p = (-3A + 0.4B) \cos 2t + (-3B - 0.4A) \sin 2t$$

$$\cos 2t = (-3A + 0.4B) \cos 2t + (-3B - 0.4A) \sin 2t$$

$$\left. \begin{aligned} 1 &= -3A + 0.4B \\ 0 &= -0.4A - 3B \end{aligned} \right\} \begin{aligned} A &= -0.3275 \\ B &= 0.0437 \end{aligned}$$

$$\ddot{y} + 0.2\dot{y} + y = \cos 2t$$

$$y = -0.375 \cos 2t + 0.0437 \sin 2t$$

$$+ C_1 e^{-0.1t} \cos(0.995t) + C_2 e^{-0.1t} \sin(0.995t)$$

Initial Conditions

zeta = 0.1 tau = 2 IC = 1 0 w0 = 1

$$y(0) = 1$$

$$\dot{y}(0) = 0$$

zeta = 0.1 tau = 2 IC = 5 -8 w0 = 1

$$y(0) = 5$$

$$\dot{y}(0) = -8$$

zeta = 0.1 tau = 2 IC = 2 2 w0 = 1

$$y(0) = 2$$

$$\dot{y}(0) = 2$$

All solutions are essentially the same
for $t > 50$. Why?

All solutions are essentially the same for $t > 50$. Why?

We want to compare the sizes of y_p and y_H so we write them in amplitude-phase form.

$$\begin{aligned} y_p &= -0.3275 \cos 2t + 0.0437 \sin 2t \\ &= 0.3304 \cos(2t - 0.116) \end{aligned}$$

$$\begin{aligned} y_H &= C_1 e^{-0.1t} \cos(0.995t) + C_2 e^{-0.1t} \sin(0.995t) \\ &= e^{-0.1t} (C_1^2 + C_2^2)^{1/2} \cos(0.995t + \arctan_2(C_2, C_1)) \end{aligned}$$

$$e^{-0.1t} \Big|_{t=50} \quad e^{-0.1 \cdot 50} = e^{-5} = 0.067$$

For $t \gg 50$ the amplitude of y_p is 0.3304, while the amplitude of y_H is less than 0.067 times the initial amplitude. y_H is so small that we can't see it on the graph. So small that it's irrelevant in many applications.

$$y_p = 0.3304 \cos(2t - 0.116)$$

constant (steady) amplitude 0.3775

$$y_H = e^{-0.1t} (C_1^2 + C_2^2)^{1/2} \cos(0.995t + \arctan_2(C_2, C_1))$$

decaying amplitude

Something which decays with time is called transient. If you wait long enough, it's gone.

When the homogeneous solution decays, we call y_p the steady state solution, and y_H the transient.

$$y = 0.3304 \cos(2t - 0.116)$$

$$+ e^{-0.1t} (C_1^2 + C_2^2)^{1/2} \cos(0.995t + \arctan_2(C_2, C_1))$$

$$y = y_{ss} + y_{tr}$$

$$y = 0.3304 \cos(2t - 0.116)$$

$$\uparrow + e^{-0.1t} (C_1^2 + C_2^2)^{1/2} \cos(0.995t + \alpha \tan^{-1}(C_2/C_1))$$

$$y = y_{ss} + y_{tr} \rightarrow$$

The steady state does not depend on the initial conditions. It only depends on the forcing term.

Only the transient part depends on the initial conditions.

The more damping, the faster the transient part decays

An Example with more damping

$$\ddot{y} + 0.8 \dot{y} + y = 3 \cos 2t$$

zeta = 0.4 tau = 2 IC = 1 0 w0 = 1

$y(0) = 1$
 $\dot{y}(0) = 0$

zeta = 0.4 tau = 2 IC = 5 -8 w0 = 1

$y(0) = 5$
 $\dot{y}(0) = -8$

zeta = 0.4 tau = 2 IC = 2 2 w0 = 1

$y(0) = 2$
 $\dot{y}(0) = 2$

$$y_H = y_{tr} = e^{-0.4t} \underbrace{A}_{\leftarrow} \cos(0.6t - \underbrace{\phi_1}_{\rightarrow})$$

These depend on IC's

$$y_p = y_{ss} = 0.8824 \cos(2t - 2.65)$$

Now only takes 10 seconds for transient to decay enough that its invisible.

$$\ddot{y} + 0.2\dot{y} + y = \cos 3t$$

You can see the $\cos(1t)$ term

$$y(0) = 1 \quad \dot{y}(0) = 0$$

$$zeta = 0.1 \quad \tau = 3 \quad IC = 1 \quad 0 \quad w_0 = 1$$

Now you only see the $\cos(3t)$ term

$$y(0) = 5 \quad \dot{y}(0) = -8$$

$$zeta = 0.1 \quad \tau = 3 \quad IC = 5 \quad -8 \quad w_0 = 1$$

$$\ddot{y} + 0.4\dot{y} + y = \cos 3t$$

$$zeta = 0.4 \quad \tau = 3 \quad IC = 1 \quad 0 \quad w_0 = 1$$

IC's

$$zeta = 0.4 \quad \tau = 3 \quad IC = 5 \quad -8 \quad w_0 = 1$$

IC's
