

Skeleton decomposition and law of large numbers for supercritical superprocesses

Zhen-Qing Chen*, Yan-Xia Ren[†] and Ting Yang[‡]

Abstract

The goal of this paper has two-folds. First, we establish skeleton and spine decompositions for superprocesses whose underlying processes are general symmetric Hunt processes. Second, we use these decompositions to obtain weak and strong law of large numbers for supercritical superprocesses where the spatial motion is a symmetric Hunt process on a locally compact metric space E and the branching mechanism takes the form

$$\psi_\beta(x, \lambda) = -\beta(x)\lambda + \alpha(x)\lambda^2 + \int_{(0, \infty)} (e^{-\lambda y} - 1 + \lambda y)\pi(x, dy)$$

with $\beta \in \mathcal{B}_b(E)$, $\alpha \in \mathcal{B}_b^+(E)$ and π being a kernel from E to $(0, \infty)$ satisfying $\sup_{x \in E} \int_{(0, \infty)} (y \wedge y^2)\pi(x, dy) < \infty$. The limit theorems are established under the assumption that an associated Schrödinger operator has a spectral gap. Our results cover many interesting examples of superprocesses, including super Ornstein-Uhlenbeck process and super stable-like process. The strong law of large numbers for supercritical superprocesses are obtained under the assumption that the strong law of large numbers for an associated supercritical branching Markov process holds along a discrete sequence of times, extending an earlier result of Eckhoff, Kyprianou and Winkel [16] for superdiffusions to a large class of superprocesses. The key for such a result is due to the skeleton decomposition of superprocess, which represents a superprocess as an immigration process along a supercritical branching Markov process.

Keywords and Phrases. law of large numbers, superprocesses, skeleton decomposition, h -transform, spectral gap

1 Introduction

Recently there is a lot of work (see [9, 16, 17, 19, 20, 21, 24, 28, 33] and the references therein) on limit theorems for superprocesses using the principal eigenvalue and ground state of the corresponding Schrödinger equations. For superdiffusions, weak (convergence in law or in probability) and strong (almost sure convergence) laws of large numbers have been established successively in [16, 17, 19, 20, 21, 28, 33]. That the underlying process is a diffusion plays an essential role in these papers. We refer to [16] for a survey on the recent developments of limit theorems for superdiffusions. Unlike the case for superdiffusions, there is much less work on limit theorems for superprocesses when the spatial motion is a general Hunt process. As far as we know, [9] is the first paper to establish strong law of large numbers (SLLN in brief) for superprocesses. The spatial motions in [9] are symmetric Hunt processes which can have discontinuous sample paths. Amongst other assumptions, a spectral gap condition was used in [9] to obtain a Poincaré inequality, which is the main ingredient in the proof of almost sure convergence along lattice times. Later [24]

used a Fourier analysis approach to establish a SLLN for super-stable processes with spatially independent quadratic branching mechanisms. Very recently, SLLN is obtained in [8] for a class of superprocesses where the spatial motion can be a non-symmetric Hunt process. In [8], the mean semigroup of the superprocess is assumed to be compact in L^2 space and the branching mechanism is assumed to satisfy a second moment condition. Under these conditions, the mean semigroup of the superprocess automatically has a spectral gap. In the existing literature for almost sure convergence, either the spatial motion has to be a diffusion, or the branching mechanism has to obey restrictive conditions (in [9] the coefficients of the branching mechanism have to satisfy a Kato class condition, while in [24, 33] the branching mechanisms are spatially independent, in [8, 9] the branching mechanisms have to satisfy a second moment condition, and in [16] it has to satisfy a p th-moment condition for some $p \in (1, 2]$).

The present paper is devoted to establish weak and strong laws of large numbers for superprocesses where the underlying spatial motions are symmetric Hunt processes and the branching mechanisms are general. A key ingredient of our approach is a *skeleton decomposition* for superprocesses, which provides a pathwise description of the superprocess in terms of immigration along a branching Markov process, called *skeleton*. The skeleton decomposition for superdiffusions was developed in [2, 26]. Very recently this decomposition was used in [16] to study limit theorems for superdiffusions. In the present paper we extend this decomposition to superprocesses whose spatial motion can be discontinuous, and use it to make a connection between the asymptotic behavior of a branching Markov process and that of a superprocess. Our proof of SLLN follows two main steps, first to obtain SLLN along lattice times and then extend it to all times. Our approach to SLLN along lattice times is different from that of [16]. Motivated by [10], where we established laws of large numbers for branching symmetric Hunt processes under a Kesten-Stigum $L \log L$ type condition, we use only L^1 -convergence technique to establish the SLLN along lattice times, whereas the approach in [16] involves a p -th moment calculation for some $p \in (1, 2]$. As a result, the branching mechanism in the present paper has to obey an $L \log L$ type condition, while the branching mechanism in [16] has to obey a p -th moment condition with $p \in (1, 2]$. So even within the superdiffusion case, our milder moment assumptions include superprocesses where the assumptions in [16] may fail (see, for example, Example 8.3 in Section 8 below). For the transition from discrete to continuous time, [16] adapted the idea of [28], where this transition is obtained through approximation of the indicator functions by resolvent functions. This idea works for superdiffusions because the spatial motion has continuous sample paths. But it is not applicable for superprocesses when the underlying motion is a general symmetric Hunt process. We overcome this difficulty by imposing a continuity condition on the h -transformed process. Examples which satisfy these assumptions are given in Section 8. In particular, the spatial motions in Example 8.4 and Example 8.5 have discontinuous paths.

The remainder of this paper is organized as follows. We start Section 2 with a review on definitions and basic properties of symmetric Hunt processes and superprocesses. A key ingredient in constructing skeleton as well as spine decomposition of superprocesses is the Kuznetsov measures or excursion measures (also known as \mathbb{N} -measures in literature) for the superprocesses. However, the existence of such a measure was taken for granted in [2, 16, 26]. In Subsection 2.3 and Appendix A.1 of this paper, we give sufficient conditions for the existence of such measures for general superprocesses and superdiffusions, respectively, and thus also filling the missing pieces in [2, 16, 26]. We then present our working hypothesis and main results in Subsection 2.4. We give a spine decomposition for the superprocess in Section 3, and then use it to prove the L^1 -convergence of an associated martingale in Section 4. In Section 5 we give a detailed description of the skeleton space for superprocesses and show that the martingale limits for the superprocess and skeleton coincide. The proofs of weak and strong laws of large numbers are given, respectively, in Section 6 and Section 7. We present several examples to illustrate our results in Section 8 and give a detailed verification of those examples in Appendix A.2 of this paper.

Throughout this paper, we use “:=” as a way of definition. For a function f , $\|f\|_\infty := \sup |f(x)|$. For

$a, b \in \mathbb{R}$, $a \wedge b := \min\{a, b\}$ and $a \vee b := \max\{a, b\}$. $\log^+ x := \log(x \vee 1)$ and

$$\log^* x := \begin{cases} x/e, & x \leq e, \\ \log x, & x > e. \end{cases}$$

For two positive functions f and g , we use $f \stackrel{c}{\asymp} g$ to denote that there is a positive constant c such that $c^{-1}f \leq g \leq cf$ on their common domain of definition. We also write \asymp for $\stackrel{c}{\asymp}$ if c is unimportant. We use $B(x, r)$ to denote the ball in \mathbb{R}^d centered at x with radius r .

2 Preliminary

2.1 Spatial process

Suppose E is a locally compact separable metric space. Let $E_\partial := E \cup \{\partial\}$ be its one point compactification. Denote by $\mathcal{B}(E)$ the Borel σ -field on E . The notation $B \Subset E$ means that its closure \bar{B} is compact in E .

We use $\mathcal{B}_b(E)$ (respectively, $\mathcal{B}^+(E)$) to denote the space of bounded (respectively, nonnegative) measurable functions on $(E, \mathcal{B}(E))$. The space of continuous (and compactly supported) functions on E will be denoted as $C(E)$ (and $C_c(E)$ resp.). Any functions f on E will be automatically extended to E_∂ by setting $f(\partial) = 0$. Suppose that m is a σ -finite nonnegative Radon measure on E with full support. When μ is a measure on $\mathcal{B}(E)$ and f is a measurable function, let $\langle f, \mu \rangle := \int_E f(x)\mu(dx)$ whenever the right hand side makes sense. In particular, if μ has a density ρ with respect to the measure m , we write $\langle f, \rho \rangle$ for $\langle f, \mu \rangle$. If $g(t, x)$ is a measurable function on $[0, \infty) \times E$, we say g is locally bounded if $\sup_{t \in [0, T]} \sup_{x \in E} g(t, x) < \infty$ for every $T \in (0, \infty)$.

Let $\xi = (\Omega, \mathcal{H}, \mathcal{H}_t, \theta_t, \xi_t, \Pi_x, \zeta)$ be an m -symmetric Hunt process on E . Here $\{\mathcal{H}_t : t \geq 0\}$ is the minimal admissible filtration, $\{\theta_t : t \geq 0\}$ the time-shift operator of ξ satisfying $\xi_t \circ \theta_s = \xi_{t+s}$ for $s, t \geq 0$, and $\zeta := \inf\{t > 0 : \xi_t = \partial\}$ the life time of ξ . Suppose for each $t > 0$, ξ has a transition density function $p(t, x, y)$ with respect to the measure m , where $p(t, x, y)$ is positive, continuous and symmetric in (x, y) . Let $\{P_t : t \geq 0\}$ be the Markovian transition semigroup of ξ , i.e.,

$$P_t f(x) := \Pi_x [f(\xi_t)] = \int_E p(t, x, y) f(y) m(dy)$$

for any nonnegative measurable function f . The symmetric Dirichlet form on $L^2(E, m)$ generated by ξ will be denoted as $(\mathcal{E}, \mathcal{F})$:

$$\mathcal{F} = \left\{ u \in L^2(E, m) : \lim_{t \rightarrow 0} \frac{1}{t} \int_E (u(x) - P_t u(x)) u(x) m(dx) < \infty \right\},$$

$$\mathcal{E}(u, v) = \lim_{t \rightarrow 0} \frac{1}{t} \int_E (u(x) - P_t u(x)) v(x) m(dx), \quad u, v \in \mathcal{F}.$$

It is known (cf. [5]) that $(\mathcal{E}, \mathcal{F})$ is quasi-regular and hence is quasi-homeomorphic to a regular Dirichlet form on a locally compact separable metric space. For any set $B \in \mathcal{B}(E)$, let $\tau_B := \inf\{t \geq 0 : \xi_t \notin B\}$.

2.2 Superprocesses

Suppose $\mathcal{M}_F(E)$ is the space of finite measures on E equipped with the topology of weak convergence. The set of finite and compactly supported measures on E is denoted by $\mathcal{M}_c(E)$. The main process of interest in this paper is an $\mathcal{M}_F(E)$ -valued Markov process $X = \{X_t : t \geq 0\}$ with evolution depending on two quantities P_t and ψ_β . Here P_t is the semigroup of the spatial process ξ and ψ_β is the so-called *branching mechanism*, which takes the form

$$\psi_\beta(x, \lambda) = -\beta(x)\lambda + \alpha(x)\lambda^2 + \int_{(0, \infty)} (e^{-\lambda y} - 1 + \lambda y) \pi(x, dy) \quad \text{for } x \in E \text{ and } \lambda \geq 0, \quad (2.1)$$

with $\beta \in \mathcal{B}_b(E)$, $\alpha \in \mathcal{B}_b^+(E)$ and for each $x \in E$, $\pi(x, dy)$ being a measure concentrated on $(0, \infty)$ such that $x \mapsto \int_{(0, \infty)} (y \wedge y^2) \pi(x, dy)$ is bounded from above. The distribution of X is denoted by P_μ if it is started in $\mu \in \mathcal{M}_F(E)$. X is called a (P_t, ψ_β) -superprocess (or (ξ, ψ_β) -superprocess) if X is an $\mathcal{M}_F(E)$ -valued process such that for all $\mu \in \mathcal{M}_F(E)$, $f \in \mathcal{B}_b^+(E)$ and $t \geq 0$,

$$P_\mu \left[e^{-\langle f, X_t \rangle} \right] = e^{-\langle u_f(t, \cdot), \mu \rangle}, \quad (2.2)$$

where $u_f(t, x) := -\log P_{\delta_x} (e^{-\langle f, X_t \rangle})$ is the unique nonnegative locally bounded solution to the following integral equation:

$$u_f(t, x) = P_t f(x) - \int_0^t P_s (\psi_\beta(\cdot, u_f(t-s, \cdot))) (x) ds \quad \text{for all } x \in E \text{ and } t \geq 0. \quad (2.3)$$

The existence of such a process X is established by [12]. Moreover, such a superprocess X has a Hunt realization in $\mathcal{M}_F(E)$ (see, for example, [27, Theorem 5.12]) such that $t \mapsto \langle f, X_t \rangle$ is almost surely right continuous for all bounded continuous functions f . We shall always work with this version.

We define the Feynman-Kac semigroup P_t^β by

$$P_t^\beta f(x) := \Pi_x \left[\exp \left(\int_0^t \beta(\xi_s) ds \right) f(\xi_t) \right] \quad \text{for } f \in \mathcal{B}_b^+(E).$$

Then it follows by [12, Lemma A.1.5] that the equation (2.3) is equivalent to the following integral equation:

$$u_f(t, x) = P_t^\beta f(x) - \int_0^t P_s^\beta (\psi_0(\cdot, u_f(t-s, \cdot))) ds \quad \text{for all } x \in E \text{ and } t \geq 0, \quad (2.4)$$

where

$$\psi_0(x, \lambda) := \alpha(x) \lambda^2 + \int_{(0, \infty)} (e^{-\lambda y} - 1 + \lambda y) \pi(x, dy).$$

It is known (cf. [12]) that for every $\mu \in \mathcal{M}_F(E)$ and $f \in \mathcal{B}_b^+(E)$, the first moment of $\langle f, X_t \rangle$ exists and can be expressed as

$$P_\mu (\langle f, X_t \rangle) = \langle P_t^\beta f, \mu \rangle. \quad (2.5)$$

Moreover, the second moment of $\langle f, X_t \rangle$, if exists, can be expressed as

$$\text{Var}_\mu (\langle f, X_t \rangle) = \int_0^t \langle P_s^\beta \left(\left(2\alpha + \int_{(0, \infty)} y^2 \pi(\cdot, dy) \right) (P_{t-s}^\beta f)^2 \right), \mu \rangle ds. \quad (2.6)$$

If $\alpha(x) + \pi(x, (0, \infty)) = 0$ for m -a.e. $x \in E$, then (2.6) implies that $\langle f, X_t \rangle = \langle P_t^\beta f, \mu \rangle$ for all $t \geq 0$ P_μ -almost surely for all $\mu \in \mathcal{M}_F(E)$ and all bounded continuous functions f . This trivial case is excluded in this paper, and we always assume that $m(\{x \in E : \alpha(x) + \pi(x, (0, \infty)) > 0\}) > 0$.

Modelling superprocess as a system of exit measures from time-space open sets has been systematically developed in [12, 13, 15]. In particular, branching property and Markov properties of such system are established there. We take $\mathcal{B}_b^+([0, t] \times E)$ to be the space of nonnegative bounded measurable functions on $[0, t] \times E$. For every $\tilde{f} \in \mathcal{B}_b^+([0, t] \times E)$, we extend \tilde{f} to $[0, t] \times \{\partial\}$ by setting $\tilde{f}(s, \partial) = 0$. It follows from [12, Theorem I.1.1 and Theorem I.1.2] that for any open set $D \subset E$ and $t \geq 0$, there exists a random measure \tilde{X}_t^D on $[0, \infty) \times E$ such that for every $\mu \in \mathcal{M}_F(E)$ and $\tilde{f} \in \mathcal{B}_b^+([0, t] \times E)$,

$$P_\mu \left[e^{-\langle \tilde{f}, \tilde{X}_t^D \rangle} \right] = e^{-\langle \tilde{u}_\tilde{f}^D(t, \cdot), \mu \rangle}, \quad (2.7)$$

where $\tilde{u}_\tilde{f}^D(t, x)$ is the unique nonnegative locally bounded solution to the following integral equation:

$$\tilde{u}_\tilde{f}^D(t, x) = \Pi_x \left[\tilde{f}(t \wedge \tau_D, \xi_{t \wedge \tau_D}) \right] - \Pi_x \left[\int_0^{t \wedge \tau_D} \psi_\beta \left(\xi_s, \tilde{u}_\tilde{f}^D(t-s, \xi_s) \right) ds \right] \quad \text{for all } x \in E \text{ and } t \geq 0. \quad (2.8)$$

Here τ_D is the first time of ξ leaving from D . For an arbitrary function $f \in \mathcal{B}_b^+(D)$, let $\tilde{f}(s, x) := f(x)$ if $x \in D$ and otherwise $\tilde{f}(s, x) = 0$. We can define a random measure X_t^D on D by setting $\langle f, X_t^D \rangle = \langle \tilde{f}, \tilde{X}_t^D \rangle$ for all $f \in \mathcal{B}_b^+(D)$. This definition implies that X_t^D is the projection of \tilde{X}_t^D on D . For $f \in \mathcal{B}_b^+(D)$, we write $u_f^D(t, x)$ for $\tilde{u}_{\tilde{f}}^D(t, x)$. It follows that $u_f^D(t, x)$ is the unique nonnegative locally bounded solution to the equation:

$$u_f^D(t, x) = \Pi_x [f(\xi_t); t < \tau_D] - \Pi_x \left[\int_0^{t \wedge \tau_D} \psi_\beta(\xi_s, u_f^D(t-s, \xi_s)) ds \right] \quad \text{for all } x \in D \text{ and } t \geq 0. \quad (2.9)$$

For an arbitrary $f \in \mathcal{B}^+(D)$, there exists a sequence of functions $f_k \in \mathcal{B}_b^+(D)$ such that $f_k \uparrow f$ pointwise. By (2.7), $u_{f_k}^D(t, x)$ is increasing in k and we denote this limit by $u_f^D(t, x) \in [0, \infty)$. With this notion, the monotone convergence theorem implies that (2.7) is valid for all $f \in \mathcal{B}^+(D)$. The same argument shows that (2.4) holds for all $f \in \mathcal{B}^+(E)$. If we define the subprocess ξ^D of ξ by

$$\xi_t^D = \begin{cases} \xi_t, & \text{if } t < \tau_D, \\ \partial, & \text{if } t \geq \tau_D, \end{cases}$$

then (2.9) is equivalent to

$$u_f^D(t, x) = \Pi_x [f(\xi_t^D)] - \Pi_x \left[\int_0^t \psi_\beta(\xi_s^D, u_f^D(t-s, \xi_s^D)) ds \right] \quad \text{for all } x \in D \text{ and } t \geq 0.$$

As a process in time, $X^D := \{X_t^D : t \geq 0\}$ is a (ξ^D, ψ_β) -superprocess. One may think of X_t^D as describing the mass of X at time t that historically avoids leaving D . The following proposition follows directly from the properties of exit measures (cf. [12, Theorem 1.2 and Theorem 1.3]). We omit its proof here.

Proposition 2.1 (monotonicity in D). *Suppose D_1 and D_2 are two open sets in E with $D_1 \subset D_2$. Then for every $\mu \in \mathcal{M}_F(E)$ and $t \geq 0$,*

$$\mathbb{P}_\mu \left(X_t^{D_1}(B) \leq X_t^{D_2}(B) \text{ for all } B \in \mathcal{B}(D_1) \right) = 1.$$

Proposition 2.1 implies that for any $f \in \mathcal{B}_b^+(D_1)$, $u_f^{D_1}(t, x) \leq u_f^{D_2}(t, x)$ for all $x \in D_1$ and $t \geq 0$. This monotonicity is also obtained in [16, Section A.2] through arguments on the integral equations (2.3) and (2.4). Although the underlying spatial motion is a diffusion in [16], their approach works generally.

2.3 Kuznetsov measures for superprocesses

Suppose $X := ((X_t)_{t \geq 0}; \mathbb{P}_\mu, \mu \in \mathcal{M}_F(E))$ is a (ξ, ψ_β) -superprocess, where the spatial motion ξ is an m -symmetric Borel right process on a Luzin topological space E with transition semigroup $(P_t)_{t \geq 0}$ and the branching mechanism ψ_β is given in (2.1). By [27, Theorem 5.12], the (ξ, ψ_β) -superprocess has a right realization in $\mathcal{M}_F(E)$. Let \mathcal{W}_0^+ denote the space of right continuous paths from $[0, \infty)$ to $\mathcal{M}_F(E)$ having null measure as a trap. Without loss of generality, we assume X_t is the coordinate process in \mathcal{W}_0^+ and that $(\mathcal{F}, (\mathcal{F}_t)_{t \geq 0})$ is the minimal augmented σ -fields on \mathcal{W}_0^+ generated by the coordinate process.

In this paper we will use two decompositions of superprocesses called spine decomposition and skeleton decomposition. To introduce these two decompositions we need to introduce Kuznetsov measures or excursion measures for superprocesses.

Let $\{Q_t(\mu, \cdot) := \mathbb{P}_\mu(X_t \in \cdot) : t \geq 0, \mu \in \mathcal{M}_F(E)\}$ be the transition semigroup of X_t and V_t be an operator on $\mathcal{B}_b^+(E)$ such that $V_t f(x) := u_f(t, x)$ for $t \geq 0$ and $f \in \mathcal{B}_b^+(E)$. Here $u_f(t, x)$ is the unique nonnegative locally bounded solution to (2.3). Then by (2.2), we have

$$\int_{\mathcal{M}_F(E)} e^{-\langle f, \nu \rangle} Q_t(\mu, d\nu) = \exp(-\langle V_t f, \mu \rangle) \quad \text{for } \mu \in \mathcal{M}_F(E) \text{ and } t \geq 0.$$

It implies that $Q_t(\mu_1 + \mu_2, \cdot) = Q_t(\mu_1, \cdot) * Q_t(\mu_2, \cdot)$ for any $\mu_1, \mu_2 \in \mathcal{M}_F(E)$, and hence $Q_t(\mu, \cdot)$ is an infinitely divisible probability measure on $\mathcal{M}_F(E)$. By the semigroup property of Q_t , V_t satisfies that

$$V_s V_t = V_{t+s} \quad \text{for all } s, t \geq 0. \quad (2.10)$$

Moreover, by the infinite divisibility of Q_t , each operator V_t has the representation

$$V_t f(x) = \int_E f(y) \Lambda_t(x, dy) + \int_{\mathcal{M}_F^+(E)} \left(1 - e^{-\langle f, \nu \rangle}\right) L_t(x, d\nu) \quad (2.11)$$

for $t > 0$ and $f \in \mathcal{B}_b^+(E)$ where $\Lambda_t(x, dy)$ is a bounded kernel on E , $\mathcal{M}_F^+(E) := \mathcal{M}_F(E) \setminus \{0\}$ and $(1 \wedge \langle 1, \nu \rangle) L_t(x, d\nu)$ is a bounded kernel from E to $\mathcal{M}_F^+(E)$. The operators $(V_t)_{t \geq 0}$ satisfying (2.10) and (2.11) is called a *cumulant semigroup*.

Let Q_t^0 be the restriction of Q_t to $\mathcal{M}_F^+(E)$, and

$$E_0 := \{x \in E : \Lambda_t(x, E) = 0 \text{ for all } t > 0\}.$$

Then $x \in E_0$ if and only if

$$V_t f(x) = \int_{\mathcal{M}_F^+(E)} \left(1 - e^{-\langle f, \nu \rangle}\right) L_t(x, d\nu) \quad \text{for all } t > 0 \text{ and } f \in \mathcal{B}_b^+(E).$$

It follows by [27, Proposition 2.8 and Theorem A.40] that for every $x \in E_0$, the family of measures $\{L_t(x, \cdot) : t > 0\}$ on $\mathcal{M}_F^+(E)$ constitutes an entrance law for the semigroup $\{Q_t^0 : t \geq 0\}$ on $\mathcal{M}_F^+(E)$. Hence it corresponds a unique σ -finite measure \mathbb{N}_x on $(\mathcal{W}_0^+, \mathcal{F})$ such that $\mathbb{N}_x(\{0\}) = 0$, and that for any $0 < t_1 < t_2 < \dots < t_n < \infty$,

$$\mathbb{N}_x(X_{t_1} \in d\nu_1, X_{t_2} \in d\nu_2, \dots, X_{t_n} \in d\nu_n) = L_{t_1}(x, d\nu_1) Q_{t_2 - t_1}^0(\nu_1, d\nu_2) \cdots Q_{t_n - t_{n-1}}^0(\nu_{n-1}, d\nu_n).$$

It follows that for all $t > 0$ and $f \in \mathcal{B}_b^+(E)$,

$$\mathbb{N}_x \left(1 - e^{-\langle f, X_t \rangle}\right) = \int_{\mathcal{M}_F^+(E)} \left(1 - e^{-\langle f, \nu \rangle}\right) L_t(x, d\nu) = u_f(t, x). \quad (2.12)$$

This measure \mathbb{N}_x is called the *Kuznetsov measure* or *excursion measure* (also known as \mathbb{N} -measure in [15]) of the (P_t, ψ_β) -superprocess corresponding to the entrance law $\{L_t(x, \cdot) : t > 0\}$, and E_0 is the collection of $x \in E$ such that there exists the Kuznetsov measure \mathbb{N}_x on $(\mathcal{W}_0^+, \mathcal{F})$ corresponding to the (P_t, ψ_β) -superprocess.

For a constant $\lambda > 0$, we use $V_t \lambda$ to denote $V_t f$ when the function $f(x) \equiv \lambda$. It follows by (2.11) that for every $x \in E$ and $t > 0$,

$$V_t \lambda(x) = \lambda \Lambda_t(x, E) + \int_{\mathcal{M}_F^+(E)} \left(1 - e^{-\lambda \langle 1, \nu \rangle}\right) L_t(x, d\nu).$$

The left hand side tends to $-\log P_{\delta_x}(X_t = 0)$ as $\lambda \rightarrow \infty$. Therefore, if $x \in E$ satisfies

$$P_{\delta_x}(X_t = 0) > 0 \quad \text{for all } t > 0, \quad (2.13)$$

then $\Lambda_t(x, E) = 0$ for all $t > 0$ and, consequently, $x \in E_0$. Thus we have

$$\{x \in E : P_{\delta_x}(X_t = 0) > 0 \text{ for all } t > 0\} \subset E_0.$$

In the study of spine decomposition, a key question is whether $\{x \in E : \alpha(x) > 0\} \subset E_0$. Later in this subsection we will give sufficient conditions for this formula to be true.

In the study of skeleton decomposition of general superprocesses, we need the following condition:

Condition 1. There is a bounded positive function w on E such that

$$P_{\delta_x} \left(e^{-\langle w, X_t \rangle} \right) = e^{-w(x)} \quad \text{for all } x \in E \text{ and } t \geq 0. \quad (2.14)$$

If the spatial motion ξ is a diffusion, then this (ξ, ψ_β) -superprocess is called a superdiffusion. We refer to Appendix A.1 for an explicit definition. When X is a superdiffusion, we only need the following condition which is weaker than Condition 1.

Condition 1'. There is a locally bounded positive function w on E satisfying (2.14).

Suppose Condition 1 holds. Since w is bounded on E , equation (2.2) implies that $u_w(t, x) = w(x)$, which is independent of $t \geq 0$. Thus by (2.4) w is the unique nonnegative bounded solution to the following integral equation:

$$w(x) + \int_0^t P_s^\beta (\psi_0(\cdot, w(\cdot))) (x) ds = P_t^\beta w(x) \quad \text{for all } x \in E. \quad (2.15)$$

It follows from the Markov property of X that for every $\mu \in \mathcal{M}_F(E)$ and $s, t \geq 0$,

$$P_\mu \left(e^{-\langle w, X_{t+s} \rangle} \mid \mathcal{F}_t \right) = P_{X_t} \left(e^{-\langle w, X_s \rangle} \right) = e^{-\langle u_w(s, \cdot), X_t \rangle} = e^{-\langle w, X_t \rangle}.$$

Hence $\{e^{-\langle w, X_t \rangle} : t \geq 0\}$ is bounded positive P_μ -martingale with respect to the filtration $(\mathcal{F}_t)_{t \geq 0}$. We now study the effects of change of measures via this martingale on the superprocess X .

Proposition 2.2. *Suppose Condition 1 is satisfied. For every $\mu \in \mathcal{M}_F(E)$, define P_μ^* by*

$$dP_\mu^* := e^{-\langle w, X_t \rangle + \langle w, \mu \rangle} dP_\mu \quad \text{on } \mathcal{F}_t \quad \text{for } t \geq 0.$$

Then for every $\mu \in \mathcal{M}_F(E)$, $f \in \mathcal{B}_b^+(E)$ and $t \geq 0$,

$$P_\mu^* \left(e^{-\langle f, X_t \rangle} \right) = e^{-\langle u_f^*(t, \cdot), \mu \rangle}, \quad (2.16)$$

and $u_f^*(t, x) = u_{w+f}(t, x) - w(x)$ is the unique nonnegative locally bounded solution to the following integral equation

$$u_f^*(t, x) + \int_0^t P_s^{\beta^*} (\psi_0^*(\cdot, u_f^*(\cdot, t-s))) (x) ds = P_t^{\beta^*} f(x) \quad \text{for } x \in E \text{ and } t \geq 0, \quad (2.17)$$

where $P_t^{\beta^*} f(x) := \Pi_x \left[\exp \left(\int_0^t \beta^*(\xi_s) ds \right) f(\xi_t) \right]$ for $f \in \mathcal{B}_b^+(E)$,

$$\beta^*(x) := \beta(x) - 2\alpha(x)w(x) - \int_{(0, \infty)} \left(1 - e^{-w(x)y} \right) y \pi(x, dy),$$

$$\psi_0^*(x, \lambda) := \alpha(x)\lambda^2 + \int_{(0, \infty)} (e^{-\lambda y} - 1 + \lambda y) \pi^*(x, dy)$$

and $\pi^*(x, dy) := e^{-w(x)y} \pi(x, dy)$.

Proof. By the definition of P^* , we have for every $\mu \in \mathcal{M}_F(E)$, $f \in \mathcal{B}_b^+(E)$ and $t \geq 0$,

$$P_\mu^* \left(e^{-\langle f, X_t \rangle} \right) = e^{\langle w, \mu \rangle} P_\mu \left(e^{-\langle w+f, X_t \rangle} \right) = e^{-\langle u_{w+f}(t, \cdot) - w(\cdot), \mu \rangle} = e^{-\langle u_f^*(t, \cdot), \mu \rangle}.$$

Recall that $u_{w+f}(t, x)$ satisfies the following equation

$$u_{w+f}(t, x) + \int_0^t P_s^\beta (\psi_0(\cdot, u_{w+f}(\cdot, t-s))) (x) ds = P_t^\beta (w+f)(x), \quad (2.18)$$

for $x \in E$ and $t \geq 0$. Using (2.15) and (2.18) it is straightforward to check that $u_f^*(t, x)$ is a nonnegative locally bounded solution to the integral equation

$$u_f^*(t, x) + \int_0^t P_s^\beta [\psi_0(\cdot, u_f^*(t-s, \cdot) + w(\cdot)) - \psi_0(\cdot, w(\cdot))] (x) ds = P_t^\beta f(x), \quad (2.19)$$

for $x \in E$ and $t \geq 0$. It then follows from [16, Lemma A.1(ii)] (by setting $A = B = E, T = t, g_1(x, s) = \beta^*(x), g_2(x, s) = \beta(x) - \beta^*(x), f_1(x) = f(x)$ and $f_2(x, s) = \psi_0(x, w(x)) - \psi_0(x, u_{w+f}(s, x))$) that $u_f^*(t, x)$ satisfying (2.19) is also a solution to (2.17). The uniqueness of the solution to (2.17) follows from [16, Appendix A.2] where the uniqueness of the solution for a more general class of integral equations is obtained. \square

Remark 2.3. If X is a superdiffusion which satisfies Condition 1', we can also define a probability measure P_μ^* such that the function $u_f^*(t, x)$ given by (2.16) is the unique nonnegative locally bounded solution to (2.17). We defer its details to Appendix A.1.

Let $\psi_{\beta^*}^*(x, \lambda) := -\beta^*(x)\lambda + \psi_0^*(x, \lambda)$ for $x \in E$ and $\lambda \geq 0$. It is easy to check that $\psi_{\beta^*}^*(x, \lambda) = \psi_\beta(x, \lambda + w(x)) - \psi_\beta(x, w(x))$. Proposition 2.2 implies that under Condition 1, $((X_t)_{t \geq 0}; P_\mu^*, \mu \in \mathcal{M}_F(E))$ is a $(\xi, \psi_{\beta^*}^*)$ -superprocess. We use Q_t^* and V_t^* to denote the transition semigroup and the cumulant semigroup of this $(\xi, \psi_{\beta^*}^*)$ -superprocess, respectively. Denote by E_0^* the collection of $x \in E$ such that there exists the Kuznetsov measure \mathbb{N}_x^* on $(\mathcal{W}_0^+, \mathcal{F})$ corresponding to the $(\xi, \psi_{\beta^*}^*)$ -superprocess. It follows that for every $x \in E_0^*$, every $t > 0$ and $f \in \mathcal{B}_b^+(E)$,

$$\mathbb{N}_x^* \left(1 - e^{-\langle f, X_t \rangle} \right) = u_f^*(t, x).$$

Applying similar argument as in the beginning of this subsection, we have

$$\{x \in E : P_{\delta_x}^*(X_t = 0) > 0 \text{ for all } t > 0\} \subset E_0^*.$$

In the study of skeleton decomposition, a key question is whether $\{x \in E : \alpha(x) > 0\} \subset E_0^*$. Sufficient conditions for this will be given at the end of this subsection.

The following assumption will be used later to establish the spine and skeleton decompositions.

Assumption 1. Suppose either one of the following conditions holds.

- (i) X is a (ξ, ψ_β) -superprocess satisfying Condition 1 and

$$E_+ := \{x \in E : \alpha(x) > 0\} \subset E_0 \cap E_0^*.$$

- (ii) X is a (ξ, ψ_β) -superdiffusion satisfying Condition 1'.

Remark 2.4. We note that $E_+ \subset E_0$ is a necessary condition for the spine decomposition while $E_+ \subset E_0^*$ is necessary for the skeleton decomposition for the (ξ, ψ_β) -superprocess X . If X is a superdiffusion that satisfies Condition 1', then $E_+ \subset E_0 \cap E_0^*$ always holds. See Appendix A.1 for its proof.

For general superprocesses, we now give some sufficient conditions for Assumption 1(i). Consider a special superprocess denoted by \tilde{X} , where the spatial motion is a conservative Borel right process on E and the branching mechanism ψ is given by

$$\psi(\lambda) := -b\lambda + a\lambda^2 + \int_{(0, \infty)} (e^{-\lambda y} - 1 + \lambda y) \eta(dy) \quad \text{for } x \in E, \lambda \geq 0, \quad (2.20)$$

where $b \in \mathbb{R}$, $a \in \mathbb{R}^+$ and η is a measure supported in $(0, \infty)$ satisfying $\int_{(0, \infty)} (x \wedge x^2) \eta(dx) < \infty$. The total mass process $\{Y_t := \langle 1, \tilde{X}_t \rangle; t \geq 0\}$ is a one-dimensional *continuous-state branching process* (CB process in abbreviation) with branching mechanism ψ . It is well-known that for the CB process Y ,

$$P_\mu [e^{-\lambda Y_t}] = e^{-v_t(\lambda) \mu(E)} \quad \text{for all } \mu \in \mathcal{M}_F(E), \lambda \geq 0 \text{ and } t \geq 0,$$

where $v_t(\lambda)$ is the unique nonnegative solution of

$$v_t(\lambda) = \lambda - \int_0^t \psi(v_s(\lambda)) ds \quad \text{for all } t, \lambda \geq 0.$$

The family of maps $\{\lambda \mapsto v_t(\lambda); t \geq 0\}$ is called the cumulant semigroup of the CB process. It follows by [27, Theorem 3.7] that $P_{\delta_x}(Y_t = 0) > 0$ for every $t > 0$ and every $x \in E$ if and only if $\psi(\infty) = \infty$ and $\int_N^\infty \psi(\lambda)^{-1} d\lambda < \infty$ for some $N > 0$. For the (ξ, ψ_β) -superprocess, the following result gives a sufficient condition under which (2.13) holds for every $x \in E$.

Proposition 2.5. *Suppose that there is a spatially independent branching mechanism ψ in the form of (2.20) such that $\psi(\infty) = \infty$, $\int^\infty \psi(\lambda)^{-1} d\lambda < \infty$, and*

$$\psi_\beta(x, \lambda) \geq \psi(\lambda) \quad \text{for all } x \in E \text{ and } \lambda \geq 0. \quad (2.21)$$

Then $P_{\delta_x}(X_t = 0) > 0$ for every $x \in E$ and every $t > 0$, and hence $E_0 = E$.

Proof. Let V_t and \hat{V}_t denote the cumulant semigroups of a (ξ, ψ_β) - and a (ξ, ψ) -superprocesses, respectively. Given (2.21), we have by [27, Corollary 5.18] (cf. [16, Lemma 4.5]) that for every $\lambda \geq 0$ and $t \geq 0$, $V_t \lambda(x) \leq \hat{V}_t \lambda(x)$ pointwise. Let $v_t(\lambda)$ be the cumulant semigroup of the CB-process with branching mechanism ψ . Then for every $\lambda \geq 0$ and $t \geq 0$, we have $\hat{V}_t \lambda(x) \leq v_t(\lambda)$ for all $x \in E$, with the equality holds if ξ is a conservative process on E . Under the conditions on ψ , we know by [27, Theorem 3.7] that $\lim_{\lambda \rightarrow \infty} v_t(\lambda) = -\log P_{\delta_x}(Y_t = 0) < \infty$ for all $t > 0$. Thus $-\log P_{\delta_x}(X_t = 0) = \lim_{\lambda \rightarrow \infty} V_t \lambda(x) < \infty$ for every $x \in E$ and $t > 0$, and hence we complete the proof. \square

Proposition 2.6. *Under Condition 1 and the condition of Proposition 2.5, we have $E_0^* = E$. Consequently, Assumption 1(i) holds.*

Proof. Since the event $\{X_t = 0\} \in \mathcal{F}_t$, it follows that

$$P_\mu^*(X_t = 0) = e^{\langle w, \mu \rangle} P_\mu \left(e^{-\langle w, X_t \rangle}; X_t = 0 \right) = e^{\langle w, \mu \rangle} P_\mu(X_t = 0)$$

for every $\mu \in \mathcal{M}_F(E)$. Thus $\{x \in E : P_{\delta_x}(X_t = 0) > 0 \text{ for all } t > 0\} = \{x \in E : P_{\delta_x}^*(X_t = 0) > 0 \text{ for all } t > 0\} \subset E_0^*$. Note that by Proposition 2.5, $\{x \in E : P_{\delta_x}(X_t = 0) > 0 \text{ for all } t > 0\} = E$. Hence we get $E_0^* = E$. \square

Remark 2.7. For the CB process Y with branching mechanism ψ , it is known that if $\psi(\infty) = \infty$ and $\int^\infty \psi(\lambda)^{-1} d\lambda < \infty$, then for every $x \in E$, $P_{\delta_x}(Y_t = 0 \text{ for some } t \geq 0) = e^{-z_\psi}$ where $z_\psi := \sup\{\lambda \geq 0 : \psi(\lambda) \leq 0\} \in [0, \infty)$. For the (ξ, ψ_β) -superprocess X , let $w(x) := -\log P_{\delta_x}(\mathcal{E})$, where the event $\mathcal{E} := \{X_t = 0 \text{ for some } t \geq 0\}$. Then under Condition (2.21), we have

$$w(x) = \lim_{t \rightarrow \infty} \lim_{\lambda \rightarrow \infty} V_t \lambda \leq \lim_{t \rightarrow \infty} \lim_{\lambda \rightarrow \infty} v_t(\lambda) = z_\psi < \infty, \quad \forall x \in E.$$

Moreover, by the bounded convergence theorem, w satisfies (2.14). In particular, if the bounded function w in Condition 1 is given by $w(x) = -\log P_{\delta_x}(\mathcal{E})$, then the process $((X_t)_{t \geq 0}; P_\mu^*, \mu \in \mathcal{M}_F(E))$ can be obtained from X by conditioning on \mathcal{E} , i.e., $P_\mu^*(X_t \in \cdot) = P_\mu(X_t \in \cdot | \mathcal{E})$, cf. [26].

2.4 Assumptions and main results

Since ξ has a transition density function $p(t, x, y)$ with respect to the measure m , it follows that for each $t > 0$, P_t^β admits an integral kernel with respect to m . We denote this kernel by $p^\beta(t, x, y)$. It is positive, symmetric and continuous in (x, y) for each $t > 0$ and it satisfies that

$$e^{-t\|\beta\|_\infty} p(t, x, y) \leq p^\beta(t, x, y) \leq e^{t\|\beta\|_\infty} p(t, x, y) \quad \text{for all } (t, x, y) \in (0, \infty) \times E \times E. \quad (2.22)$$

This semigroup P_t^β associates with a quadratic form $(\mathcal{E}^{(\beta)}, \mathcal{F})$, where

$$\mathcal{E}^{(\beta)}(u, u) := \mathcal{E}(u, u) - \int_E u(x)^2 \beta(x) m(dx), \quad u \in \mathcal{F}.$$

Since β is a bounded function, $\mathcal{E}^{(\beta)}(u, u) \geq -\|\beta\|_\infty \int_E u(x)^2 m(dx)$ for all $u \in \mathcal{F}$. Thus by [1], $\{P_t^\beta : t \geq 0\}$ is a strongly continuous semigroup on $L^2(E, m)$. We define

$$\lambda_1 := \inf \left\{ \mathcal{E}^{(\beta)}(u, u) : u \in \mathcal{F} \text{ with } \int_E u(x)^2 m(dx) = 1 \right\}. \quad (2.23)$$

Obviously $\lambda_1 \geq -\|\beta^+\|_\infty$ by definition.

Assumption 2. $\lambda_1 < 0$ and there is a positive continuous function $h \in \mathcal{F}$ with $\int_E h(x)^2 m(dx) = 1$ so that $\mathcal{E}^{(\beta)}(h, h) = \lambda_1$.

Observe that if u is a minimizer for (2.23), then so is $|u|$. Hence one can always take a non-negative minimizer. Assumption 2 requires that there is a minimizer for (2.23) that can be chosen to be positive everywhere. Clearly the following property holds for h :

$$\mathcal{E}^\beta(h, v) = \lambda_1 \langle h, v \rangle \quad \text{for every } v \in \mathcal{F}. \quad (2.24)$$

Let $\sigma(\mathcal{E}^{(\beta)})$ denote the spectrum of the self-adjoint operator associated with $\mathcal{E}^{(\beta)}$. Then λ_1 is a simple eigenvalue in $\sigma(\mathcal{E}^{(\beta)})$ with eigenfunction h . It holds that $h = e^{\lambda_1 t} P_t^\beta h$ on E .

Remark 2.8. From the definition of $\mathcal{E}^{(\beta)}$, Assumption 2 implies that $m(\{x \in E : \beta(x) > 0\}) > 0$.

Let λ_2 be the second bottom of $\sigma(\mathcal{E}^{(\beta)})$, that is,

$$\lambda_2 := \inf \left\{ \mathcal{E}^{(\beta)}(u, u) : u \in \mathcal{F}, \int_E u(x) h(x) m(dx) = 0, \int_E u(x)^2 m(dx) = 1 \right\}.$$

Assumption 3. There is a positive spectral gap in $\sigma(\mathcal{E}^{(\beta)})$: $\lambda_h := \lambda_2 - \lambda_1 > 0$.

Define the h -transformed semigroup $\{P_t^h; t \geq 0\}$ from $\{P_t^\beta; t \geq 0\}$ by

$$P_t^h f(x) = \frac{e^{\lambda_1 t}}{h(x)} P_t^\beta(hf)(x) \quad \text{for } x \in E \text{ and } f \in \mathcal{B}_b^+(E). \quad (2.25)$$

Then it is easy to see that $\{P_t^h : t \geq 0\}$ is an \tilde{m} -symmetric semigroup, where $\tilde{m} := h^2 m$, and 1 is an eigenfunction of P_t^h with eigenvalue 1. Furthermore the spectrum of the infinitesimal generator of $\{P_t^h : t \geq 0\}$ in $L^2(E; \tilde{m})$ is the spectrum of the infinitesimal generator of $\{P_t^\beta : t \geq 0\}$ in $L^2(E; m)$ shifted by λ_1 . Hence under Assumption 3, we have the following Poincaré inequality:

$$\|P_t^h \varphi\|_{L^2(E, \tilde{m})} \leq e^{-\lambda_h t} \|\varphi\|_{L^2(E, \tilde{m})} \quad (2.26)$$

for all $\varphi \in L^2(E, \tilde{m})$ with $\int_E \varphi(x) \tilde{m}(dx) = 0$.

We use $\mathcal{M}_F^h(E)$ to denote the space of all finite measures μ on E with $\langle h, \mu \rangle < \infty$. By (2.5) and the fact that $e^{\lambda_1 t} P_t^\beta h = h$, we can verify that under Assumption 2,

$$W_t^h(X) := e^{\lambda_1 t} \langle h, X_t \rangle \quad \text{for } t \geq 0$$

is a nonnegative P_μ -martingale for all $\mu \in \mathcal{M}_F^h(E)$. We define $W_\infty^h(X) := \lim_{t \rightarrow \infty} W_t^h(X)$.

Theorem 2.9. *Suppose Assumptions 1-3 hold. If*

$$\langle \alpha \log^+ h, h^2 \rangle + \left\langle \int_{(0, \infty)} r \log^*(rh(\cdot)) \pi(\cdot, dr), h^2 \right\rangle < \infty, \quad (2.27)$$

then the non-negative martingale $W_t^h(X)$ converges to $W_\infty^h(X)$ as $t \rightarrow \infty$ \mathbb{P}_μ -a.s. and in $L^1(\mathbb{P}_\mu)$ for every $\mu \in \mathcal{M}_F^h(E)$. In particular, $W_\infty^h(X)$ is non-degenerate in the sense that $\mathbb{P}_\mu(W_\infty^h(X) > 0) > 0$ for any nontrivial $\mu \in \mathcal{M}_F^h(E)$.

Remark 2.10. We notice that only the spine decomposition of superprocesses is applied in the proof of this theorem. Therefore the above result in fact holds with the same proof under a weaker condition, say, Assumptions 2-3 and that $E_+ \subset E_0$.

As we mentioned earlier, Assumption 1 is a fundamental assumption for the existence of the skeleton space. The skeleton space for supercritical superprocesses offers a pathwise description of the superprocess in terms of an $\mathcal{M}_F(E)$ -valued Markov process X^* and a supercritical branching Markov process Z dressed with an immigration process I on a rich probability space with probability measures \mathbb{P}_μ . A more detailed description and discussion of skeleton space is deferred to Section 5. In [26], the skeleton space was constructed for superdiffusions using the function $w(x) = -\log P_{\delta_x}(\exists t \geq 0 : \langle 1, X_t \rangle = 0)$. The key property of w used in the skeleton construction is that w gives rise to the multiplicative \mathbb{P}_μ -martingale $\{e^{-\langle w, X_t \rangle} : t \geq 0\}$. Later the skeleton space is established in [16] for superdiffusions assuming only the existence of such a martingale function w . The main reason why skeleton space is constructed only for superdiffusions in [26] and [16] is due to the proof of [26, Lemma 6.1], where a comparison principle for elliptic differential operators is used. This comparison principle allows one to conclude that if B_1 and B_2 are domains with $\text{supp}(f) \subseteq B_1 \subseteq B_2$, then $u_f^{B_1}(t, x) \leq u_f^{B_2}(t, x)$ pointwise. Proposition 2.1 implies that this monotonicity in fact holds more generally as in the set-up of this paper, where the underlying spatial motion can be discontinuous. Therefore we can establish the existence of skeleton space for superprocesses defined in Section 5.

In Theorem 2.11 below we show that under Assumptions 1-3,

$$W_t^{h/w}(Z) := e^{\lambda_1 t} \left\langle \frac{h}{w}, Z_t \right\rangle \quad \text{for } t \geq 0$$

equals $W_t^h(X)$ and so is a nonnegative \mathbb{P}_μ -martingale for all $\mu \in \mathcal{M}_F^h(E)$. Let $W_\infty^{h/w}(Z) := \lim_{t \rightarrow \infty} W_t^{h/w}(Z)$.

Theorem 2.11. *Suppose Assumptions 1-3 hold. For every $\mu \in \mathcal{M}_F^h(E)$ and $t \geq 0$, $W_t^h(X) = W_t^{h/w}(Z)$ \mathbb{P}_μ -a.s. and in particular $W_\infty^h(X) = W_\infty^{h/w}(Z)$ \mathbb{P}_μ -a.s.*

The proof of Theorem 2.11 will be given in Section 5. We will establish laws of large numbers under the following moment conditions.

Assumption 4.

- (i) ($L \log L$ condition) $\langle \log^+ h, h^2 \rangle + \left\langle \int_{(0, \infty)} r \log^*(rh(\cdot)) \pi(\cdot, dr), h^2 \right\rangle < \infty$.
- (ii) $\left\langle \left(\int_{(0, \infty)} r^2 e^{-w(\cdot)r} \pi(\cdot, dr) \right)^2, 1 \wedge h^4 \right\rangle < \infty$.

Theorem 2.12 (Weak law of large numbers). *Suppose Assumptions 1-3 and Assumption 4(i) hold. Then for all $\mu \in \mathcal{M}_F^h(E)$ and all $f \in \mathcal{B}^+(E)$ with f/h bounded,*

$$\lim_{t \rightarrow \infty} e^{\lambda_1 t} \langle f, X_t \rangle = \langle f, h \rangle W_\infty^h(X) \quad \text{in } L^1(\mathbb{P}_\mu).$$

The proof of Theorem 2.12 will be given in Section 6. The next assumption assumes that the strong law of large numbers holds for the supercritical branching Markov process Z along an increasing sequence of discrete times.

Assumption 5. For all $\mu \in \mathcal{M}_c(E)$, $\sigma > 0$ and $\phi \in \mathcal{B}_b^+(E)$,

$$\lim_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \left\langle \frac{h}{w} \phi, Z_{n\sigma} \right\rangle = \langle \phi, h^2 \rangle W_\infty^{h/w}(Z) \quad \mathbb{P}_\mu\text{-a.s.}$$

We will prove at the end of Section 6 that under Assumptions 1-3 and Assumption 4(i), Assumption 5 is equivalent to a weaker condition as follows.

Assumption 5'. For all $\mu \in \mathcal{M}_c(E)$, $\sigma > 0$ and $\phi \in \mathcal{B}_b^+(E)$, there exists $m \in \mathbb{N}$ such that

$$\lim_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \left\langle \frac{h}{w} P_{m\sigma}^h \phi, Z_{n\sigma} \right\rangle = \langle \phi, h^2 \rangle W_\infty^{h/w}(Z) \quad \mathbb{P}_\mu\text{-a.s.}$$

Assumption 6. The semigroup $\{P_t^h : t \geq 0\}$ satisfies that

$$\lim_{t \rightarrow 0} \|P_t^h f - f\|_\infty = 0 \quad \text{for all } f \in C_0(E).$$

Here $C_0(E) := \{f \in C(E) \text{ with } \lim_{x \rightarrow \partial} f(x) = 0\}$.

The following is the main result of this paper, which extends the main results of [16, 28] to superprocesses having possibly discontinuous spatial motions. Its proof will be given in Section 7.

Theorem 2.13 (Strong law of large numbers). *Suppose Assumptions 1-6 hold. Then there exists $\Omega_0 \subset \Omega$ of \mathbb{P}_μ -full probability for every $\mu \in \mathcal{M}_F^h(E)$ such that on Ω_0 , for every m -almost everywhere continuous nonnegative measurable function f with f/h bounded, we have*

$$\lim_{t \rightarrow \infty} e^{\lambda_1 t} \langle f, X_t \rangle = \langle f, h \rangle W_\infty^h(X). \quad (2.28)$$

The convergence in (2.28) also holds in $L^1(\mathbb{P}_\mu)$.

3 Change of measures

Recall that $h \in \mathcal{F}$ is the minimizer in Assumption 2. Since $h \in \mathcal{F}$, by Fukushima's decomposition, we have for q.e. $x \in E$, Π_x -a.s.

$$h(\xi_t) - h(\xi_0) = M_t^h + N_t^h \quad \text{for } t \geq 0,$$

where M_t^h is a martingale additive functional of ξ having finite energy and N_t^h is a continuous additive functional of ξ having zero energy. It follows from (2.24) and [22, Theorem 5.4.2] that N_t^h is of bounded variation, and

$$N_t^h = -\lambda_1 \int_0^t h(\xi_s) ds - \int_0^t h(\xi_s) \beta(\xi_s) ds \quad \text{for } t \geq 0.$$

Following [4, Section 2] (see also [10, Section 2]), we define a local martingale on the random time interval $[0, \zeta_p)$ by

$$M_t := \int_0^t \frac{1}{h(\xi_{s-})} dM_s^h, \quad t \in [0, \zeta_p), \quad (3.1)$$

where ζ_p is the predictable part of the life time ζ of ξ . Then the solution R_t of the stochastic differential equation

$$R_t = 1 + \int_0^t R_{s-} dM_s, \quad t \in [0, \zeta_p), \quad (3.2)$$

is a positive local martingale on $[0, \zeta_p)$ and hence a supermartingale. As a result, the formula

$$d\Pi_x^h = R_t d\Pi_x \quad \text{on } \mathcal{H}_t \cap \{t < \zeta\} \quad \text{for } x \in E$$

uniquely determines a family of subprobability measures $\{\Pi_x^h : x \in E\}$ on (Ω, \mathcal{H}) . We denote ξ under $\{\Pi_x^h : x \in E\}$ by ξ^h , that is

$$\Pi_x^h [f(\xi_t^h)] = \Pi_x [R_t f(\xi_t) : t < \zeta] \quad \text{for all } t \geq 0 \text{ and } f \in \mathcal{B}_b^+(E).$$

It follows from [4, Theorem 2.6] that the process ξ^h is an irreducible recurrent \tilde{m} -symmetric right Markov process, where $\tilde{m}(dy) = h(y)^2 m(dy)$. Note that by (3.1), (3.2) and Doléan-Dade's formula,

$$R_t = \exp \left(M_t - \frac{1}{2} \langle M^c \rangle_t \right) \prod_{0 < s \leq t} \frac{h(\xi_s)}{h(\xi_{s-})} \exp \left(1 - \frac{h(\xi_s)}{h(\xi_{s-})} \right), \quad t \in [0, \zeta_p), \quad (3.3)$$

where M^c is the continuous martingale part of M . Applying Ito's formula to $\log h(\xi_t)$, we obtain that for q.e. $x \in E$, Π_x -a.s. on $[0, \zeta)$,

$$\log h(\xi_t) - \log h(\xi_0) = M_t - \frac{1}{2} \langle M^c \rangle_t + \sum_{s \leq t} \left(\log \frac{h(\xi_s)}{h(\xi_{s-})} - \frac{h(\xi_s) - h(\xi_{s-})}{h(\xi_{s-})} \right) - \lambda_1 t - \int_0^t \beta(\xi_s) ds. \quad (3.4)$$

By (3.3) and (3.4), we get

$$R_t = \exp \left(\lambda_1 t + \int_0^t \beta(\xi_s) ds \right) \frac{h(\xi_t)}{h(\xi_0)} \quad \text{on } [0, \zeta).$$

Therefore for any $f \in \mathcal{B}_b^+(E)$,

$$\Pi_x^h (f(\xi_t^h)) = \frac{e^{\lambda_1 t}}{h(x)} \Pi_x \left(e^{\int_0^t \beta(\xi_s) ds} h(\xi_t) f(\xi_t) \right) = \frac{e^{\lambda_1 t}}{h(x)} P_t^\beta (hf)(x) = P_t^h f(x).$$

This implies that the transition semigroup of ξ^h is exactly the semigroup $\{P_t^h : t \geq 0\}$ obtained from P_t^β through Doob's h -transform. Let $(\mathcal{E}^h, \mathcal{F}^h)$ be the symmetric Dirichlet form in $L^2(E; \tilde{m})$ generated by ξ^h . Then $f \in \mathcal{F}^h$ if and only if $fh \in \mathcal{F}$, and

$$\mathcal{E}^h(f, f) = \mathcal{E}^{(\beta)}(fh, fh) - \lambda_1 \int_E f(x)^2 h(x)^2 m(dx).$$

In other words, $\Phi^h : f \mapsto fh$ is an isometry from $(\mathcal{E}^h, \mathcal{F}^h)$ onto $(\mathcal{E}^{\beta + \lambda_1 m}, \mathcal{F})$ and from $L^2(E, \tilde{m})$ onto $L^2(E, m)$. Let $\sigma(\mathcal{E}^h)$ denote the spectrum of $-\tilde{\mathcal{L}}$, where $\tilde{\mathcal{L}}$ is the self-adjoint operator associated with the Dirichlet form $(\mathcal{E}^h, \mathcal{F}^h)$ in $L^2(E; \tilde{m})$. We know from [4, Theorem 2.6] that the constant function 1 belongs to \mathcal{F}^h , and $\mathcal{E}^h(1, 1) = 0$. Hence $0 \in \sigma(\mathcal{E}^h)$ is a simple eigenvalue and 1 is the corresponding eigenfunction. In particular,

$$\lambda_1^h := \inf \left\{ \mathcal{E}^h(u, u) : u \in \mathcal{F}^h \text{ with } \int_E u(x)^2 \tilde{m}(dx) = 1 \right\} = 0.$$

Let λ_2^h be the second bottom of $\sigma(\mathcal{E}^h)$, i.e.

$$\lambda_2^h := \inf \left\{ \mathcal{E}^h(u, u) : u \in \mathcal{F}^h \text{ with } \int_E u(x) \tilde{m}(dx) = 0 \text{ and } \int_E u(x)^2 \tilde{m}(dx) = 1 \right\}.$$

In view of the isometry Φ^h , we have $\lambda_2^h = \lambda_2 - \lambda_1$. So Assumption 3 is equivalent to assuming $\lambda_2^h > 0$. The h -transformed process ξ^h has a transition density function $p^h(t, x, y)$ with respect to \tilde{m} , which is positive, symmetric and continuous in (x, y) for each $t > 0$ and is related to $p^\beta(t, x, y)$ by

$$p^h(t, x, y) = e^{\lambda_1 t} \frac{p^\beta(t, x, y)}{h(x)h(y)} \quad \text{for } x, y \in E \text{ and } t \geq 0. \quad (3.5)$$

Define

$$\tilde{a}_t(x) := p^h(t, x, x) \quad \text{for } t > 0 \text{ and } x \in E.$$

Using the Poincaré inequality (2.26), we can prove that (cf. [10]) for every $g \in L^2(E, \tilde{m})$,

$$|P_t^h g(x) - \langle g, h^2 \rangle| \leq e^{-\lambda_h(t-s)} \tilde{a}_{2s}(x)^{1/2} \|g\|_{L^2(E, \tilde{m})}. \quad (3.6)$$

Moreover for $t > s > 0$ and $x, y \in E$,

$$|p^h(t, x, y) - 1| \leq e^{-\lambda_h(t-s)} \tilde{a}_s(x)^{1/2} \tilde{a}_s(y)^{1/2}. \quad (3.7)$$

For $\mu \in \mathcal{M}_F^h(E)$ with $\mu \neq 0$, we use $\Pi_{h\mu}^h$ to denote the probability measure where ξ^h is the recurrent motion with starting point randomised according to $\frac{h(x)\mu(dx)}{\langle h, \mu \rangle}$. In other words,

$$\Pi_{h\mu}^h(\cdot) = \frac{1}{\langle h, \mu \rangle} \int_E \Pi_x^h(\cdot) h(x) \mu(dx).$$

Since $W_t^h(X)$ is a nonnegative P_μ -martingale, we can define a new probability measure Q_μ by

$$dQ_\mu := \frac{W_t^h(X)}{\langle h, \mu \rangle} dP_\mu \quad \text{on } \sigma(X_s; s \in [0, t]).$$

The next result can be proved in the same way as that for [16, Lemma 2.17].

Lemma 3.1. *Suppose Assumption 2 holds. For all $\mu \in \mathcal{M}_F^h(E)$ with $\mu \neq 0$, $f, g \in \mathcal{B}_b^+(E)$ and $t \geq 0$, we have*

$$Q_\mu \left[e^{-\langle f, X_t \rangle} \frac{\langle gh, X_t \rangle}{\langle h, X_t \rangle} \right] = P_\mu \left[e^{-\langle f, X_t \rangle} \Pi_{h\mu}^h \left[g(\xi_t) \exp \left(- \int_0^t \frac{\partial \psi_0}{\partial \lambda}(\xi_s, u_f(t-s, \xi_s)) ds \right) \right] \right],$$

where $u_f(t, x)$ is the unique nonnegative locally bounded solution to the integral equation (2.3).

It follows from Lemma 3.1 that

$$\begin{aligned} & Q_\mu \left[e^{-\langle f, X_t \rangle} \right] \\ &= P_\mu \left[e^{-\langle f, X_t \rangle} \Pi_{h\mu}^h \left[\exp \left(- \int_0^t \frac{\partial \psi_0}{\partial \lambda}(\xi_s, u_f(t-s, \xi_s)) \right) \right] \right] \\ &= P_\mu \left[e^{-\langle f, X_t \rangle} \Pi_{h\mu}^h \left[\exp \left(- \int_0^t 2\alpha(\xi_s) u_f(t-s, \xi_s) ds - \int_0^t \int_{(0, \infty)} \left(1 - e^{-u_f(t-s, \xi_s)y} \right) y \pi(\xi_s, dy) ds \right) \right] \right]. \end{aligned}$$

This formula offers a probabilistic view of the superprocess X_t under the new measure Q_μ that is stated in the following proposition.

Proposition 3.2. *Suppose Assumption 2 holds and that $E_+ \subset E_0$. For every $\mu \in \mathcal{M}_F^h(E)$ with $\mu \neq 0$, there exists a probability space with probability measure $Q_{h\mu}$ that carries the following processes*

- (i) $((\xi_t)_{t \geq 0}; Q_{h\mu})$ is equal in distribution to $((\xi_t)_{t \geq 0}; \Pi_{h\mu}^h)$. We call $((\xi_t)_{t \geq 0}; Q_{h\mu})$ the spine.
- (ii) $(n; Q_{h\mu})$ is a random measure such that given $(\xi, Q_{h\mu})$, n is a Poisson random measure which issues $\mathcal{M}_F(E)$ -valued processes $X_s^{n,t} := \{X_s^{n,t}; s \geq 0\}$ at space-time point (ξ_t, t) with rate

$$d\mathbb{N}_{\xi_t} \times 2\alpha(\xi_t) dt.$$

Here for every $x \in E_+ = \{x \in E : \alpha(x) > 0\}$, \mathbb{N}_x is the Kuznetsov measure on \mathcal{W}_0^+ corresponding to the (P_t, ψ_β) -superprocess, while for $x \notin E_+$ \mathbb{N}_x is the null measure on \mathcal{W}_0^+ . Note that, given ξ , the immigration happens only at space-time point (ξ_t, t) with $\alpha(\xi_t) > 0$. Let D^n denote the almost surely countable set of immigration times, and $D_t^n := D^n \cap [0, t]$. Given ξ , the processes $\{X_s^{n,t} : t \in D^n\}$ are mutually independent. We refer to $\{X_s^{n,t} : t \in D^n\}$ as the continuous immigration.

(iii) $(m; \mathbb{Q}_{h\mu})$ is a random measure such that given ξ , m is a Poisson random measure which issues $\mathcal{M}_F(E)$ -valued processes $X^{m,t} := (X_s^{m,t})_{s \geq 0}$ at space-time point (ξ_t, t) with initial mass y at rate

$$y\pi(\xi_t, dy) \times dP_{y\delta_{\xi_t}} \times dt.$$

Here $P_{y\delta_x}$ denotes the law of the (P_t, ψ_β) -superprocess starting in $y\delta_x$. Let D^m denote the almost surely countable set of immigration times, and $D_t^m := D^m \cap [0, t]$. Given ξ , the processes $\{X^{m,t} : t \in D^m\}$ are mutually independent and independent of n and $\{X^{n,t} : t \in D^n\}$. We refer to $\{X^{m,t} : t \in D^m\}$ as the discontinuous immigration.

(iv) $((X_t)_{t \geq 0}; \mathbb{Q}_{h\mu})$ is equal in distribution to $((X_t)_{t \geq 0}; P_\mu)$. Moreover $((X_t)_{t \geq 0}; \mathbb{Q}_{h\mu})$ is independent of ξ , n , m and all immigration processes.

Let $X_t^n := \sum_{s \in D_t^n} X_{t-s}^{n,s}$ and $X_t^m := \sum_{s \in D_t^m} X_{t-s}^{m,s}$. Define

$$\Gamma_t := X_t + X_t^n + X_t^m \text{ for } t \geq 0.$$

Then $(\Gamma := (\Gamma_t)_{t \geq 0}; \mathbb{Q}_{h\mu})$ is equal in distribution to $(X := (X_t)_{t \geq 0}; \mathbb{Q}_\mu)$.

The proof of Proposition 3.2 is similar to that of [25, Theorem 5.2] so it is omitted here. For $s \geq 0$, define

$$I_s^m := \langle 1, X_0^{m,s} \rangle \quad \text{if } s \in D^m \quad \text{and} \quad I_s^m := 0 \quad \text{elsewise.}$$

Then, given ξ , $\{I_s^m, s \geq 0\}$ is a Poisson point process with characteristic measure $y\pi(\xi_s, dy)$. Let \mathcal{G} be the σ -field generated by ξ , the random measures n and m , and the process $\{I_s^m, s \geq 0\}$.

Lemma 3.3. For $\mu \in \mathcal{M}_F^h(E)$ with $\mu \neq 0$, $f \in \mathcal{B}_b^+(E)$ and $t \geq 0$,

$$\mathbb{Q}_{h\mu} [\langle f, \Gamma_t \rangle | \mathcal{G}] = \langle P_t^\beta f, \mu \rangle + \sum_{s \in D_t^n} P_{t-s}^\beta f(\xi_s) + \sum_{s \in D_t^m} I_s^m P_{t-s}^\beta f(\xi_s) \quad \mathbb{Q}_{h\mu}\text{-a.s.} \quad (3.8)$$

Proof. By (2.12), we have for every $x \in E_0$, $f \in \mathcal{B}_b^+(E)$ and $t > 0$,

$$\mathbb{N}_x (\langle f, X_t \rangle) = P_{\delta_x} (\langle f, X_s \rangle) = P_t^\beta f(x).$$

Thus by the definition of Γ_t , under $\mathbb{Q}_{h\mu}$,

$$\begin{aligned} \mathbb{Q}_{h\mu} [\langle f, \Gamma_t \rangle | \mathcal{G}] &= \mathbb{Q}_{h\mu} (\langle f, X_t \rangle) + \sum_{s \in D_t^n} \mathbb{Q}_{h\mu} [\langle f, X_{t-s}^{n,s} \rangle | \mathcal{G}] + \sum_{s \in D_t^m} \mathbb{Q}_{h\mu} [\langle f, X_{t-s}^{m,s} \rangle | \mathcal{G}] \\ &= P_\mu (\langle f, X_t \rangle) + \sum_{s \in D_t^n} \mathbb{N}_{\xi_s} (\langle f, X_{t-s} \rangle) + \sum_{s \in D_t^m} P_{I_s^m \delta_{\xi_s}} (\langle f, X_{t-s} \rangle) \\ &= \langle P_t^\beta f, \mu \rangle + \sum_{s \in D_t^n} P_{t-s}^\beta f(\xi_s) + \sum_{s \in D_t^m} I_s^m P_{t-s}^\beta f(\xi_s). \end{aligned}$$

□

By the monotone convergence theorem, (3.8) holds for any $f \in \mathcal{B}^+(E)$. We call formula (3.8) the *spine decomposition* for $((X_t)_{t \geq 0}; \mathbb{Q}_\mu)$.

4 Martingale convergence of $W_t^h(X)$

In this section we prove Theorem 2.9 under Assumptions 1-3.

Lemma 4.1. $g(x) := h(x)^{-1} P_{\delta_x} (W_\infty^h(X))$ is a constant function on E .

Proof. We first claim that for any $\mu \in \mathcal{M}_F^h(E)$,

$$\mathbb{P}_\mu(W_\infty^h(X)) = \int_E \mathbb{P}_{\delta_x}(W_\infty^h(X)) \mu(dx). \quad (4.1)$$

The proof of this claim is the same as that of [30, Lemma 5.4], we omit its details here. By the Markov property of X , we have for any $t \geq 0$ and $x \in E$,

$$\begin{aligned} g(x) &= \frac{1}{h(x)} \mathbb{P}_{\delta_x} \left[\lim_{s \rightarrow \infty} e^{\lambda_1(t+s)} \langle h, X_{t+s} \rangle \right] \\ &= \frac{e^{\lambda_1 t}}{h(x)} \mathbb{P}_{\delta_x} \left[\mathbb{P}_{X_t} \left(\lim_{s \rightarrow \infty} W_s^h(X) \right) \right] \\ &= \frac{e^{\lambda_1 t}}{h(x)} \mathbb{P}_{\delta_x} \left[\mathbb{P}_{X_t}(W_\infty^h(X)) \right]. \end{aligned}$$

This together with (4.1) implies that

$$g(x) = \frac{e^{\lambda_1 t}}{h(x)} \mathbb{P}_{\delta_x}(\langle gh, X_t \rangle) = \frac{e^{\lambda_1 t}}{h(x)} P_t^\beta(gh)(x) = P_t^h g(x).$$

This means that g is an invariant function for the irreducible recurrent process $(\xi^h; \Pi^h)$. Hence g is a constant function on E . \square

Proof of Theorem 2.9: Without loss of generality, we assume $\mu \in \mathcal{M}_F^h(E)$ and $\mu \neq 0$. Since $W_t^h(X)$ is a nonnegative martingale, to show it is a closed martingale, it suffices to prove

$$\mathbb{P}_\mu(W_\infty^h(X)) = \langle h, \mu \rangle. \quad (4.2)$$

First we claim that (4.2) is true for $\mu_B(dy) := 1_B(y)h(y)m(dy)$ with $B \Subset E$ and $m(B) \neq 0$. It is straightforward to see from the change of measure methodology (see, for example, [11, Theorem 5.3.3]) that the proof for this claim is completed as soon as we can show that

$$\mathbb{Q}_{\mu_B} \left(\limsup_{t \rightarrow \infty} W_t^h(X) < \infty \right) = 1. \quad (4.3)$$

Since $((X_t)_{t \geq 0}; \mathbb{Q}_{\mu_B})$ is equal in distribution to $((\Gamma_t)_{t \geq 0}; \mathbb{Q}_{h\mu_B})$, (4.3) is equivalent to that

$$\mathbb{Q}_{h\mu_B} \left(\limsup_{t \rightarrow \infty} W_t^h(\Gamma) < \infty \right) = 1. \quad (4.4)$$

Recall that \mathcal{G} is the σ -field generated by ξ , n , m and $\{I_s^m, s \geq 0\}$. By the spine decomposition formula (3.8), for any $t > 0$,

$$\begin{aligned} \mathbb{Q}_{h\mu_B}(W_t^h(\Gamma)|\mathcal{G}) &= e^{\lambda_1 t} \langle P_t^\beta h, \mu_B \rangle + e^{\lambda_1 t} \sum_{s \in D_t^n} P_{t-s}^\beta h(\xi_s) + e^{\lambda_1 t} \sum_{s \in D_t^m} I_s^m P_{t-s}^\beta h(\xi_s) \\ &= \langle h, \mu_B \rangle + \sum_{s \in D_t^n} e^{\lambda_1 s} h(\xi_s) + \sum_{s \in D_t^m} e^{\lambda_1 s} I_s^m h(\xi_s) \\ &\leq \langle h, \mu_B \rangle + \sum_{s \in D_t^n} e^{\lambda_1 s} h(\xi_s) + \sum_{s \in D_t^m} e^{\lambda_1 s} I_s^m h(\xi_s). \end{aligned} \quad (4.5)$$

Applying almost the same argument as in the proof of [30, Theorem 5.1], we can show that the last two terms in (4.5) are finite almost surely, and hence $\limsup_{t \rightarrow \infty} \mathbb{Q}_{h\mu_B}(W_t^h(\Gamma)|\mathcal{G}) < \infty$ $\mathbb{Q}_{h\mu_B}$ -a.s. By Fatou's lemma, $\mathbb{Q}_{h\mu_B}(\liminf_{t \rightarrow \infty} W_t^h(\Gamma) < \infty) = 1$. Note that $W_t^h(\Gamma)^{-1}$ is a nonnegative $\mathbb{Q}_{h\mu_B}$ -supermartingale. Hence

$$\mathbb{Q}_{h\mu_B} \left(\limsup_{t \rightarrow \infty} W_t^h(\Gamma) < \infty \right) = 1.$$

This proves (4.4) and consequently,

$$P_{\mu_B} (W_\infty^h(X)) = \langle h, \mu_B \rangle. \quad (4.6)$$

Note that $P_{\mu_B} (W_\infty^h(X)) = \langle P_{\delta_x} (W_\infty^h(X)), \mu_B \rangle$ by (4.1) and then

$$\langle P_{\delta_x} (W_\infty^h(X)), \mu_B \rangle = \langle h, \mu_B \rangle. \quad (4.7)$$

By Fatou's lemma, for every $x \in E$, $P_{\delta_x} (W_\infty^h(X)) \leq h(x)$. We get by (4.7) that $P_{\delta_x} (W_\infty^h(X)) = h(x)$ m -a.e. on B . Since B is arbitrary, $P_{\delta_x} (W_\infty^h(X)) = h(x)$ m -a.e. on E and hence everywhere on E by Lemma 4.1. Therefore by (4.1), $P_\mu (W_\infty^h(X)) = \langle h, \mu \rangle$ holds for all $\mu \in \mathcal{M}_F^h(E)$. This completes the proof. \square

5 Skeleton space

In this section, we work under Assumptions 1-3. We first consider general superprocess case, for which as a part of Assumption 1, Condition 1 holds and w is the bounded positive function in (2.14). By (2.2) and (2.3), $u_w(t, x) = w(x)$ is the unique nonnegative bounded solution to the following equation:

$$w(x) = P_t w(x) - \int_0^t P_s (\psi_\beta(\cdot, w(\cdot)))(x) ds \quad \text{for every } x \in E \text{ and } t \geq 0. \quad (5.1)$$

Note that

$$\frac{\psi_\beta(x, \lambda)}{\lambda} = -\beta(x) + a(x)\lambda + \frac{1}{\lambda} \int_{(0, \infty)} (e^{-\lambda y} - 1 + \lambda y) \pi(x, dy), \quad (5.2)$$

which is a bounded function on $E \times (0, M]$ for every $M > 0$. Let

$$M_t := w(\xi_t) - \int_0^t \psi_\beta(\xi_s, w(\xi_s)) ds,$$

which is bounded in $t \in [0, T]$ for every $T > 0$. Let $\{\mathcal{H}_t : t \geq 0\}$ be the minimal augmented σ -fields generated by the process $\xi = \{\xi_t, t \geq 0; \Pi_x, x \in E\}$. By the Markov property of ξ_t and (5.1), we have for every $t > s \geq 0$ and $x \in E$,

$$\begin{aligned} \Pi_x [M_t | \mathcal{H}_s] &= \Pi_{\xi_s} [w(\xi_{t-s}) - \int_0^s \psi_\beta(\xi_r, w(\xi_r)) dr] - \Pi_{\xi_s} \left[\int_0^{t-s} \psi_\beta(\xi_r, w(\xi_r)) dr \right] \\ &= P_{t-s} w(\xi_s) - \Pi_{\xi_s} \left[\int_0^{t-s} \psi_\beta(\cdot, w(\cdot)) dr \right] - \int_0^s \psi_\beta(\xi_r, w(\xi_r)) dr \\ &= w(\xi_s) - \int_0^s \psi_\beta(\xi_r, w(\xi_r)) dr = M_s. \end{aligned}$$

In other words, $\{M_t; t \geq 0\}$ is a martingale additive functional of ξ . Observe that it follows from (5.2) that

$$\gamma(x) := \frac{\psi_\beta(x, w(x))}{w(x)}$$

is a bounded function. Since $w(\xi_t) = M_t + \int_0^t \psi_\beta(\xi_s, w(\xi_s)) ds$, we have by Ito's formula

$$\begin{aligned} d \left(w(\xi_t) e^{-\int_0^t \gamma(\xi_s) ds} \right) &= -w(\xi_t) \gamma(\xi_t) e^{-\int_0^t \gamma(\xi_s) ds} dt + e^{-\int_0^t \gamma(\xi_s) ds} (dM_t + \psi_\beta(\xi_t, w(\xi_t)) dt) \\ &= e^{-\int_0^t \gamma(\xi_s) ds} dM_t. \end{aligned}$$

Thus we have shown that $t \mapsto w(\xi_t) e^{-\int_0^t \gamma(\xi_s) ds}$ is a martingale.

Next we consider the superdiffusion case, for which Assumption 1 is just Condition 1'; that is, there is a locally bounded positive function w satisfying (2.14). By truncating w and then using the monotone convergence theorem, one can prove that

$$w(x) = \Pi_x [w(\xi_{t \wedge \tau_B})] - \Pi_x \left[\int_0^{t \wedge \tau_B} \psi_\beta(\xi_s, w(\xi_s)) ds \right]$$

for any bounded open set $B \Subset E$. Since $x \mapsto w(x)$ is bounded on B , one can generalize the above argument and show that $t \mapsto w(\xi_{t \wedge \tau_B}) \exp\left(-\int_0^{t \wedge \tau_B} \gamma(\xi_s) ds\right)$ is a nonnegative Π_x -martingale. This implies that $\{w(\xi_t) \exp\left(-\int_0^t \gamma(\xi_s) ds\right) : t \geq 0\}$ is a nonnegative Π_x -local martingale and hence a Π_x -supermartingale.

Hence in both cases we can define a family of (sub)probability measures $\{\Pi_x^w : x \in E\}$ on \mathcal{H} by

$$d\Pi_x^w := \frac{w(\xi_t)}{w(x)} \exp\left(-\int_0^t \frac{\psi_\beta(\xi_s, w(\xi_s))}{w(\xi_s)} ds\right) d\Pi_x \quad \text{on } \mathcal{H}_t \quad \text{for every } t \geq 0.$$

Clearly, the transformed process $\xi^w := ((\xi_t)_{t \geq 0}; \Pi_x^w, x \in E)$ is a Borel right process. Through the arguments after Remark 2.10, we can also construct the skeleton space for a (P_t, ψ_β) -superprocesses as follows.

Proposition 5.1. *Suppose Assumptions 1-3 hold. Let $\mathcal{M}_A^{loc}(E)$ denote the set of locally finite integer-valued measures on $(E, \mathcal{B}(E))$. For every $\mu \in \mathcal{M}_F(E)$ and every $\nu \in \mathcal{M}_A^{loc}(E)$, there exists a probability space with probability measure $\mathbb{P}_{\mu, \nu}$ that carries the following processes:*

- (i) $(Z := (Z_t)_{t \geq 0}; \mathbb{P}_{\mu, \nu})$ is a supercritical branching Markov process with spatial motion ξ^w , branching rate function $q(x)$ and offspring distribution function $\{p_k(x) : k \geq 2\}$ uniquely defined by

$$G(x, s) := q(x) \sum_{k=2}^{\infty} p_k(x) (s^k - s) := \frac{1}{w(x)} (\psi_0(x, (1-s)w(x)) - (1-s)\psi_0(x, w(x))), \quad (5.3)$$

and $\mathbb{P}_{\mu, \nu}(Z_0 = \nu) = 1$. We use the classical Ulam-Harris notations to refer to the particles in the genealogical tree \mathcal{T} of Z . For a particle $u \in \mathcal{T}$, we use b_u and d_u for its birth and death times, and $z_u(t)$ for its spatial location at time $t \in [b_u, d_u]$.

- (ii) $(X^* := (X_t^*)_{t \geq 0}; \mathbb{P}_{\mu, \nu})$ is a $(P_t, \psi_{\beta^*}^*)$ -superprocess with $\mathbb{P}_{\mu, \nu}(X_0^* = \mu) = 1$ such that for all $\mu \in \mathcal{M}_F(E)$, $f \in \mathcal{B}_b^+(E)$ and $t \geq 0$,

$$\mathbb{P}_{\mu, \nu} \left[e^{-\langle f, X_t^* \rangle} \right] = e^{-\langle u_j^*(t, \cdot), \mu \rangle}, \quad (5.4)$$

where $u_j^*(t, x)$ is the unique nonnegative locally bounded solution to equation (2.17), and $\psi_{\beta^*}^*(x, \lambda) := -\beta^*(x)\lambda + \psi_0^*(x, \lambda)$ is given in Proposition 2.2. By (2.17) and (5.4), the mean of $\langle f, X_t^* \rangle$ can be expressed by

$$\mathbb{P}_{\mu, \nu}(\langle f, X_t^* \rangle) = \langle P_t^{\beta^*} f, \mu \rangle \quad \text{for } f \in \mathcal{B}_b^+(E).$$

The distribution of X^* under $\mathbb{P}_{\mu, \nu}$ does not depend on ν . Moreover, under $\mathbb{P}_{\mu, \nu}$, X^* is independent of Z .

- (iii) $(I := (I_t)_{t \geq 0}; \mathbb{P}_{\mu, \nu})$ is a $\mathcal{M}_F(E)$ -valued process with $\mathbb{P}_{\mu, \nu}(I_0 = 0) = 1$, which is given by $I = I^{\mathbf{a}} + I^{\mathbf{b}}$ where $I^{\mathbf{a}}$ and $I^{\mathbf{b}}$ are described as follows:

- (a) $(\mathbf{a}; \mathbb{P}_{\mu, \nu})$ is a random measure such that given Z , \mathbf{a} is a Poisson random measure that issues for every $u \in \mathcal{T}$, $\mathcal{M}_F(E)$ -valued processes $X^{\mathbf{a}, u, r} := (X_t^{\mathbf{a}, u, r})_{t \geq 0}$ along the space-time trajectory $\{(z_u(r), r) : r \in (b_u, d_u)\}$ with rate

$$\left(2\alpha(z_u(r)) d\mathbb{N}_{z_u(r)}^* + \int_{(0, \infty)} y \pi^*(z_u(r), dy) \times d\mathbb{P}_{y \delta_{z_u(r)}}^* \right) \times dr,$$

where \mathbb{P}_μ^* is the law of the $(P_t, \psi_{\beta^*}^*)$ -superprocess starting in μ , for every $x \in E_+ = \{x \in E : \alpha(x) > 0\}$, \mathbb{N}_x^* denotes the Kuznetsov measure on \mathcal{W}_0^+ corresponding to the $(P_t, \psi_{\beta^*}^*)$ -superprocess, and for $x \notin E_+$, \mathbb{N}_x^* is the null measure on \mathcal{W}_0^+ . The processes $\{X^{\mathbf{a},u,r} : u \in \mathcal{T}, r \in (b_u, d_u]\}$ are independent of X^* , and, given Z , are mutually independent.

$$I_t^{\mathbf{a}} := \sum_{u \in \mathcal{T}} \sum_{r \in (b_u, d_u \wedge t]} X_{t-r}^{\mathbf{a},u,r} \quad \text{for } t \geq 0.$$

- (b) $(\mathbf{b}; \mathbb{P}_{\mu,\nu})$ is a random measure such that given Z , \mathbf{b} issues for every $u \in \mathcal{T}$, at space-time point $(z_u(d_u), d_u)$, an $\mathcal{M}_F(E)$ -valued process $X^{\mathbf{b},u} := (X_t^{\mathbf{b},u})_{t \geq 0}$ with law $\mathbb{P}_{Y_u \delta_{z_u(d_u)}}^*$ such that given that u gives birth to k particles at its death time, the independent \mathbb{R}^+ -valued random variable Y_u is distributed according to the measure

$$\frac{1}{q(x)w(x)p_k(x)} \left(\alpha(x)w(x)^2 \delta_0(dy) 1_{\{k=2\}} + w(x)^k \frac{y^k}{k!} \pi^*(x, dy) \right) \Big|_{x=z_u(d_u)}.$$

The processes $\{X^{\mathbf{b},u} : u \in \mathcal{T}\}$ are independent of X^* , and, given Z , are mutually independent and independent of \mathbf{a} .

$$I_t^{\mathbf{b}} := \sum_{u \in \mathcal{T}} 1_{\{d_u \leq t\}} X_{t-d_u}^{\mathbf{b},u} \quad \text{for } t \geq 0.$$

For every $\mu \in \mathcal{M}_F(E)$, let \mathbb{P}_μ denote the measure $\mathbb{P}_{\mu,\nu}$ with ν replaced by a Poisson random measure with intensity $w(x)\mu(dx)$. Then $(\widehat{X} := X^* + I; \mathbb{P}_\mu)$ is Markovian and has the same distribution as $(X; \mathbb{P}_\mu)$. Moreover, under \mathbb{P}_μ , given \widehat{X}_t , the measure Z_t is a Poisson random measure with intensity $w(x)\widehat{X}_t(dx)$.

With the results from Subsection 2.3 and Appendix A.1 on the existence of \mathbb{N}_x^* under Assumption 1, the proof of Proposition 5.1 is very similar to that of [26, Corollary 2] and we omit its long computations here. We call the probability space in Proposition 5.1 the *skeleton space*. The process Z is called *skeleton process* and I is called *immigration process*. We call $(X^* + I; \mathbb{P}_\mu)$ the skeleton decomposition of X . Since $(\widehat{X}; \mathbb{P}_\mu)$ is equal in distribution to the (P_t, ψ_β) -superprocess $(X; \mathbb{P}_\mu)$, we may work on this skeleton space whenever it is convenient. For notational simplification, we will abuse the notation and denote \widehat{X} by X . Since the distributions of X^* (resp. I) under $\mathbb{P}_{\mu,\nu}$ do not depend on ν (resp. μ), we sometimes write $\mathbb{P}_{\mu,\cdot}$ (resp. $\mathbb{P}_{\cdot,\nu}$) for $\mathbb{P}_{\mu,\nu}$.

For $t \geq 0$, we write $Z_t = \sum_{i=1}^{N_t} \delta_{z_i(t)}$ where N_t denotes the number of skeleton particles at time t and $\{z_i(t) : i = 1, \dots, N_t\}$ their spatial locations. Let $m(x) := \sum_{k=2}^{\infty} kp_k(x)$. We have by (5.3) that $q(x)(m(x) - 1) = \frac{\partial G}{\partial s}(x, s)|_{s=1} = \psi_0(x, w(x))/w(x)$. Then by the many-to-one formula for branching Markov process (cf. [31, Lemma 3.3]), for $f \in \mathcal{B}_b^+(E)$, $x \in E$ and $t \geq 0$,

$$\begin{aligned} \mathbb{P}_{\cdot, \delta_x}(\langle f, Z_t \rangle) &= \Pi_x^w \left[\exp \left(\int_0^t q(\xi_s)(m(\xi_s) - 1) ds \right) f(\xi_t) \right] \\ &= \frac{1}{w(x)} \Pi_x \left[\exp \left(\int_0^t \frac{-\psi_\beta(\xi_s, w(\xi_s)) + \psi_0(\xi_s, w(\xi_s))}{w(\xi_s)} ds \right) w(\xi_t) f(\xi_t) \right] \\ &= \frac{1}{w(x)} P_t^\beta(wf)(x). \end{aligned} \tag{5.5}$$

Note that under \mathbb{P}_μ with $\mu \in \mathcal{M}_F(E)$, Z_0 is a Poisson random measure with intensity $w(x)\mu(dx)$. We get from (5.5) that

$$\mathbb{P}_\mu(\langle f, Z_t \rangle) = \mathbb{P}_\mu \left(\sum_{i=1}^{N_0} \mathbb{P}_{\cdot, \delta_{z_i(0)}}(\langle f, Z_t \rangle) \right) = \mathbb{P}_\mu \left(\langle \frac{1}{w} P_t^\beta(wf), Z_0 \rangle \right) = \langle P_t^\beta(wf), \mu \rangle. \tag{5.6}$$

For $t \geq 0$, let \mathcal{F}_t denote the σ -field generated by Z , X^* and I up to time t . Denote by $I_s^{*,t}$ the immigration at time $t + s$ that occurred along the skeleton before time t . For $i \in \{1, 2, \dots, N_t\}$, denote by $I_s^{i,t}$ the

immigration at time $t + s$ that occurred along the subtree of the skeleton rooted at the i th particle with location $z_i(t)$. We have

$$X_{s+t} = X_{s+t}^* + I_s^{*,t} + \sum_{i=1}^{N_t} I_s^{i,t} \quad \text{for all } s, t \geq 0.$$

We know by [16] that, given \mathcal{F}_t , $(X_{s+t}^* + I_s^{*,t})_{s \geq 0}$ is equal in distribution to $((X_s^*)_{s \geq 0}; \mathbb{P}_{X_t})$ and $I^{i,t} := (I_s^{i,t})_{s \geq 0}$ is equal in distribution to $(I; \mathbb{P}_{\cdot, \delta_{z_i(t)}})$. Moreover, the processes $\{I^{i,t} : i = 1, 2, \dots, N_t\}$ are mutually independent. Using these properties, we have for $\mu \in \mathcal{M}_F(E)$, $f \in \mathcal{B}_b^+(E)$ and $t, s \geq 0$, under \mathbb{P}_μ

$$\begin{aligned} \mathbb{P}_\mu (\langle f, X_{t+s} \rangle | \mathcal{F}_t) &= \mathbb{P}_\mu (\langle f, X_{t+s}^* + I_s^{*,t} \rangle | \mathcal{F}_t) + \mathbb{P}_\mu \left(\sum_{i=1}^{N_t} \langle f, I_s^{i,t} \rangle \middle| \mathcal{F}_t \right) \\ &= \mathbb{P}_{X_t} (\langle f, X_s^* \rangle) + \sum_{i=1}^{N_t} \mathbb{P}_{\cdot, \delta_{z_i(t)}} (\langle f, I_s \rangle). \end{aligned} \quad (5.7)$$

Note that under \mathbb{P}_μ , N_0 is a Poisson random variable with mean $\langle w, \mu \rangle$. We have for each $x \in E$,

$$\begin{aligned} \mathbb{P}_{\delta_x} (\langle f, I_t \rangle) &= \mathbb{P}_{\delta_x} \left(\sum_{i=1}^{N_0} \mathbb{P}_{\cdot, \delta_{z_i(0)}} (\langle f, I_t \rangle) \right) \\ &= \mathbb{P}_{\delta_x} (N_0 \mathbb{P}_{\cdot, \delta_x} (\langle f, I_t \rangle)) = w(x) \mathbb{P}_{\cdot, \delta_x} (\langle f, I_t \rangle). \end{aligned} \quad (5.8)$$

Thus $\mathbb{P}_{\cdot, \delta_x} (\langle f, I_t \rangle) = w(x)^{-1} \mathbb{P}_{\delta_x} (\langle f, I_t \rangle) = w(x)^{-1} \mathbb{P}_{\delta_x} (\langle f, X_t - X_t^* \rangle) = w(x)^{-1} (P_t^\beta f(x) - P_t^{\beta*} f(x))$. Using this and (5.7), we have for every $\mu \in \mathcal{M}_F(E)$, $f \in \mathcal{B}_b^+(E)$ and $s, t \geq 0$,

$$\mathbb{P}_\mu [\langle f, X_{t+s} \rangle | \mathcal{F}_t] = \langle P_s^{\beta*} f, X_t \rangle + \left\langle \frac{P_s^\beta f}{w}, Z_t \right\rangle - \left\langle \frac{P_s^{\beta*} f}{w}, Z_t \right\rangle \quad \mathbb{P}_\mu\text{-a.s.} \quad (5.9)$$

By the monotone convergence theorem, the boundedness of f in (5.9) is unnecessary and (5.9) holds for $f \in \mathcal{B}^+(E)$ which satisfies $\langle P_t^\beta f, \mu \rangle < \infty$ for any $t \geq 0$,

Lemma 5.2. *Suppose Assumptions 1-3 hold. For every $f \in \mathcal{B}^+(E)$ so that f/h is bounded, define*

$$\theta_f^*(t, x) := \frac{e^{\lambda_1 t}}{h(x)} P_t^{\beta*} f(x) \quad \text{for } x \in E \text{ and } t \geq 0.$$

Then $\theta_f^*(t, x)$ is bounded on $[0, \infty) \times E$, and for every $x \in E$,

$$\theta_f^*(t, x) \rightarrow 0 \text{ as } t \rightarrow \infty.$$

Proof. Let $g(x) := \beta(x) - \beta^*(x) = 2\alpha(x)w(x) + \int_{(0, \infty)} (1 - e^{-w(x)y}) y \pi(x, dy) \in \mathcal{B}^+(E)$ and $c_1 := \sup_{x \in E} f(x)/h(x) \in [0, \infty)$. By the definition, for every $x \in E$ and $t \geq 0$

$$\begin{aligned} \theta_f^*(t, x) &= \frac{e^{\lambda_1 t}}{h(x)} \Pi_x \left[\exp \left(\int_0^t \beta^*(\xi_s) ds \right) f(\xi_t) \right] \\ &= \frac{e^{\lambda_1 t}}{h(x)} \Pi_x \left[\exp \left(\int_0^t \beta(\xi_s) - g(\xi_s) ds \right) h(\xi_t) \frac{f(\xi_t)}{h(\xi_t)} \right] \\ &= \Pi_x^h \left[\exp \left(- \int_0^t g(\xi_s) ds \right) \frac{f(\xi_t)}{h(\xi_t)} \right] \\ &\leq c_1 \Pi_x^h \left[\exp \left(- \int_0^t g(\xi_s) ds \right) \right]. \end{aligned}$$

Immediately $\theta_f^*(t, x) \leq c_1$ for all $(t, x) \in [0, \infty) \times E$. Let $l(x) := \Pi_x^h \left[\exp \left(- \int_0^\infty g(\xi_s) ds \right) \right]$. To prove the second claim of this lemma, it suffices to prove that $l(x) \equiv 0$ on E . Let $A := \{x \in E : g(x) > 0\} = \{x \in E :$

$\alpha(x) + \pi(x, (0, \infty)) > 0\}$. We have $\tilde{m}(A) > 0$ since $m(A) > 0$. For an arbitrary $M > 0$ and $x \in E$, define $P_M(x) := \Pi_x^h(\int_0^\infty g(\xi_s)ds > M)$. By the Markov property of ξ , for $t \geq 0$ and $x \in E$,

$$\begin{aligned} P_t^h P_M(x) &= \Pi_x^h \left[\Pi_{\xi_t}^h \left(\int_0^\infty g(\xi_s)ds > M \right) \right] \\ &= \Pi_x^h \left(\int_t^\infty g(\xi_s)ds > M \right) \\ &\leq P_M(x). \end{aligned}$$

Moreover, $\lim_{t \rightarrow 0} P_t^h P_M(x) = P_M(x)$ by the monotone convergence theorem. Hence $P_M(x)$ is an excessive function for the irreducible recurrent process $(\xi^h; \Pi^h)$. It follows from [5, Lemma 3.5 and Lemma A.2.17] that P_M is a constant function on E . We claim that there exists $M_1 > 0$ and $c_2 \in (0, 1]$ such that

$$P_{M_1}(x) \geq c_2 > 0 \quad \text{for all } x \in E. \quad (5.10)$$

If (5.10) is not true, that is, $P_M(x) \equiv 0$ for all $M > 0$, then $\Pi_x^h(\int_0^\infty g(\xi_s)ds = 0) = 1$. This contradicts the fact that $\Pi_x^h(\int_0^\infty g(\xi_s)ds) = \int_0^\infty \int_A p^h(s, x, y)g(y)\tilde{m}(dy)ds > 0$ since $\tilde{m}(A) > 0$ and $p^h(s, x, \cdot)$ is positive on A . In view of (5.10), we have

$$l(x) = \Pi_x^h \left[\exp \left(- \int_0^\infty g(\xi_s)ds \right) \right] \leq c_2 e^{-M_1} + (1 - c_2) =: c_3 < 1.$$

Thus by the Markov property of ξ , for any $t > 0$,

$$\begin{aligned} l(x) &= \Pi_x^h \left[\exp \left(- \int_0^t g(\xi_s)ds \right) \exp \left(- \int_t^\infty g(\xi_s)ds \right) \right] \\ &= \Pi_x^h \left[\exp \left(- \int_0^t g(\xi_s)ds \right) l(\xi_t) \right] \\ &\leq c_3 \Pi_x^h \left[\exp \left(- \int_0^t g(\xi_s)ds \right) \right]. \end{aligned} \quad (5.11)$$

Letting $t \rightarrow \infty$ in (5.11), we get $l(x) \leq c_3^2$ for all $x \in E$. Applying the above argument recursively for n times, we get $l(x) \leq c_3^n$ for all $x \in E$. Hence we conclude $l(x) \equiv 0$ by letting $n \rightarrow \infty$. \square

Proof of Theorem 2.11: We only need to prove the first claim. For any $t, s \geq 0$, by the skeleton decomposition (5.9), we have under \mathbb{P}_μ

$$\begin{aligned} W_t^h(X) &= \mathbb{P}_\mu(W_{t+s}^h(X) | \mathcal{F}_t) \\ &= e^{\lambda_1(t+s)} \mathbb{P}_\mu(\langle h, X_{t+s} \rangle | \mathcal{F}_t) \\ &= e^{\lambda_1(t+s)} \left(\langle P_s^{\beta^*} h, X_t \rangle + \left\langle \frac{P_s^\beta h}{w}, Z_t \right\rangle - \left\langle \frac{P_s^{\beta^*} h}{w}, Z_t \right\rangle \right) \\ &= e^{\lambda_1 t} \langle \theta_h^*(s, \cdot) h, X_t \rangle + e^{\lambda_1 t} \left\langle \frac{h}{w}, Z_t \right\rangle - e^{\lambda_1 t} \langle \theta_h^*(s, \cdot) \frac{h}{w}, Z_t \rangle \\ &= e^{\lambda_1 t} \langle \theta_h^*(s, \cdot) h, X_t \rangle + W_t^{h/w}(Z) - e^{\lambda_1 t} \langle \theta_h^*(s, \cdot) \frac{h}{w}, Z_t \rangle. \end{aligned} \quad (5.12)$$

Letting $s \rightarrow \infty$, the first term and the third term in (5.12) converge to 0 \mathbb{P}_μ -almost surely by Lemma 5.2 and the dominated convergence theorem and hence we get $W_t^h(X) = W_t^{h/w}(Z)$ \mathbb{P}_μ -a.s. \square

6 Weak law of large numbers

Throughout this section, we assume Assumptions 1-3 and Assumption 4(i) hold.

Lemma 6.1. For any $\phi \in \mathcal{B}_b^+(E)$ and $t > 0$,

$$\int_E P_{\delta_x} (\langle \phi h, X_t \rangle \log^+ \langle \phi h, X_t \rangle) h(x) m(dx) < \infty.$$

Proof. Note that for $\phi \in \mathcal{B}_b^+(E)$ and $x \in E$,

$$\begin{aligned} P_{\delta_x} (\langle \phi h, X_t \rangle \log^+ \langle \phi h, X_t \rangle) &\leq e^{-\lambda_1 t} \|\phi\|_\infty P_{\delta_x} (e^{\lambda_1 t} \langle h, X_t \rangle \log^+ \langle \phi h, X_t \rangle) \\ &= e^{-\lambda_1 t} \|\phi\|_\infty h(x) Q_{\delta_x} (\log^+ \langle \phi h, X_t \rangle) \\ &= e^{-\lambda_1 t} \|\phi\|_\infty h(x) Q_{h\delta_x} (\log^+ \langle \phi h, \Gamma_t \rangle). \end{aligned} \quad (6.1)$$

Using the fact $\log^+(a+b) \leq \log^+ a + \log^+ b + \log 2$ for $a, b \geq 0$ and Jensen inequality, we have

$$\begin{aligned} Q_{h\delta_x} (\log^+ \langle \phi h, \Gamma_t \rangle) &= Q_{h\delta_x} [Q_{h\delta_x} (\log (\langle \phi h, \Gamma_t \rangle \vee 1) | \mathcal{G})] \\ &\leq Q_{h\delta_x} [\log Q_{h\delta_x} (\langle \phi h, \Gamma_t \rangle \vee 1 | \mathcal{G})] \\ &\leq Q_{h\delta_x} [\log^+ (Q_{h\delta_x} (\langle \phi h, \Gamma_t \rangle | \mathcal{G}) + 1)] \\ &\leq Q_{h\delta_x} [\log^+ Q_{h\delta_x} (\langle \phi h, \Gamma_t \rangle | \mathcal{G})] + \log 2. \end{aligned} \quad (6.2)$$

Thus by (6.1) and (6.2), we only need to prove that

$$\int_E Q_{h\delta_x} [\log^+ Q_{h\delta_x} (\langle \phi h, \Gamma_t \rangle | \mathcal{G})] h(x)^2 m(dx) < \infty. \quad (6.3)$$

By the spine decomposition formula (3.8), we have under $Q_{h\delta_x}$

$$\begin{aligned} Q_{h\delta_x} (\langle \phi h, \Gamma_t \rangle | \mathcal{G}) &\leq \|\phi\|_\infty Q_{h\delta_x} (\langle h, \Gamma_t \rangle | \mathcal{G}) \\ &= \|\phi\|_\infty e^{-\lambda_1 t} \left(h(x) + \sum_{s \in D_t^n} e^{\lambda_1 s} h(\xi_s) + \sum_{s \in D_t^m} e^{\lambda_1 s} I_s^m h(\xi_s) \right). \end{aligned}$$

Using the fact that $\log^+(ab) \leq \log^+ a + \log^+ b$ for $a, b \geq 0$, we have

$$\begin{aligned} \log^+ Q_{h\delta_x} (\langle \phi h, \Gamma_t \rangle | \mathcal{G}) &\leq \log^+ (e^{-\lambda_1 t} \|\phi\|_\infty) + \log^+ h(x) + \sum_{s \in D_t^n} \log^+ (e^{\lambda_1 s} h(\xi_s)) \\ &\quad + \sum_{s \in D_t^m} \log^+ (e^{\lambda_1 s} I_s^m h(\xi_s)) + \sum_{s \in D_t^n \cup D_t^m} \log 2. \end{aligned}$$

Assumption 4(i) implies that $\int_E \log^+ h(x) h(x)^2 m(dx) < \infty$. Hence to prove (6.3), it suffices to prove

$$\int_E Q_{h\delta_x} \left[\sum_{s \in D_t^n} (\log^+ (e^{\lambda_1 s} h(\xi_s)) + 1) + \sum_{s \in D_t^m} (\log^+ (e^{\lambda_1 s} I_s^m h(\xi_s)) + 1) \right] \tilde{m}(dx) < \infty. \quad (6.4)$$

Since $\lambda_1 < 0$, we have by Fubini's theorem and the \tilde{m} -symmetry of $(\xi^h; \Pi^h)$ that

$$\begin{aligned} &\int_E Q_{h\delta_x} \left[\sum_{s \in D_t^n} (\log^+ (e^{\lambda_1 s} h(\xi_s)) + 1) \right] \tilde{m}(dx) \\ &= \int_E Q_{h\delta_x} \left[\int_0^t 2\alpha(\xi_s) (\log^+ (e^{\lambda_1 s} h(\xi_s)) + 1) \right] \tilde{m}(dx) \\ &= 2 \int_0^t ds \int_E \Pi_x^h [\alpha(\xi_s) (\log^+ (e^{\lambda_1 s} h(\xi_s)) + 1)] \tilde{m}(dx) \\ &= 2 \int_0^t ds \int_E \alpha(x) (\log^+ (e^{\lambda_1 s} h(x)) + 1) \tilde{m}(dx) \end{aligned}$$

$$\begin{aligned}
&\leq 2 \int_0^t ds \int_E \alpha(x) (\log^+ h(x) + 1) \tilde{m}(dx) \\
&\leq 2 \|\alpha\|_\infty t \left(1 + \int_E \log^+ h(x) h(x)^2 m(dx) \right) < \infty.
\end{aligned}$$

Similarly by (2.27), we have

$$\begin{aligned}
&\int_E \mathbb{Q}_{h\delta_x} \left[\sum_{s \in D_t^m} (\log^+(e^{\lambda_1 s} I_s^m h(\xi_s)) + 1) \right] \tilde{m}(dx) \\
&= \int_E \Pi_x^h \left[\int_0^t ds \left(\int_{(0,\infty)} \log^+(e^{\lambda_1 s} r h(\xi_s)) r \pi(\xi_s, dr) + 1 \right) \right] \tilde{m}(dx) \\
&= t + \int_0^t ds \int_E \Pi_x^h \left[\int_{(0,\infty)} r \log^+(e^{\lambda_1 s} r h(\xi_s)) \pi(\xi_s, dr) \right] \tilde{m}(dx) \\
&= t + \int_0^t ds \langle \int_{(0,\infty)} r \log^+(e^{\lambda_1 s} r h(\cdot)) \pi(\cdot, dr), h^2 \rangle \\
&\leq t + t \langle \int_{(0,\infty)} r \log^+(r h(\cdot)) \pi(\cdot, dr), h^2 \rangle \\
&\leq t + t \langle \int_{(0,\infty)} r \log^*(r h(\cdot)) \pi(\cdot, dr), h^2 \rangle < \infty.
\end{aligned}$$

This completes the proof for (6.4). \square

Lemma 6.2. For any $\mu \in \mathcal{M}_c(E)$ and $\phi \in \mathcal{B}_b^+(E)$,

$$\lim_{s \rightarrow \infty} \lim_{t \rightarrow \infty} e^{\lambda_1(s+t)} \langle \phi h, X_{s+t}^* + I_s^{*,t} \rangle = 0 \quad \text{in } L^1(\mathbb{P}_\mu).$$

Proof. Recall that given \mathcal{F}_t , $(X_{s+t}^* + I_s^{*,t})_{s \geq 0}$ is equal in distribution to $((X_s^*)_{s \geq 0}; \mathbb{P}_{X_t})$. Thus by Markov property,

$$\begin{aligned}
e^{\lambda_1(s+t)} \mathbb{P}_\mu (\langle \phi h, X_{s+t}^* + I_s^{*,t} \rangle) &= e^{\lambda_1(s+t)} \mathbb{P}_\mu [\mathbb{P}_\mu (\langle \phi h, X_{s+t}^* + I_s^{*,t} \rangle | \mathcal{F}_t)] \\
&= e^{\lambda_1(s+t)} \mathbb{P}_\mu [\mathbb{P}_{X_t} (\langle \phi h, X_s^* \rangle)] \\
&= e^{\lambda_1(s+t)} \mathbb{P}_\mu [\langle P_s^{\beta^*}(\phi h), X_t \rangle] \\
&= e^{\lambda_1 t} \mathbb{P}_\mu (\langle h \theta_{\phi h}^*(s, \cdot), X_t \rangle) \\
&= e^{\lambda_1 t} \langle P_t^\beta(h \theta_{\phi h}^*(s, \cdot)), \mu \rangle \\
&= \langle h P_t^h(\theta_{\phi h}^*(s, \cdot)), \mu \rangle.
\end{aligned}$$

Thus we have

$$\begin{aligned}
\limsup_{t \rightarrow \infty} e^{\lambda_1(s+t)} \mathbb{P}_\mu (\langle \phi h, X_{s+t}^* + I_s^{*,t} \rangle) &= \limsup_{t \rightarrow \infty} \langle h P_t^h(\theta_{\phi h}^*(s, \cdot)), \mu \rangle \\
&\leq \langle \limsup_{t \rightarrow \infty} P_t^h(\theta_{\phi h}^*(s, \cdot)), h \mu \rangle.
\end{aligned} \tag{6.5}$$

We get by (3.6) that for $t > 1$ and $x \in E$

$$P_t^h(\theta_{\phi h}^*(s, \cdot))(x) \leq \int_E \theta_{\phi h}^*(s, x) \tilde{m}(dx) + e^{-\lambda_h(t-1)} \tilde{a}_2(x)^{1/2} \|\theta_{\phi h}^*(s, \cdot)\|_{L^2(E, \tilde{m})}.$$

This implies that

$$\limsup_{t \rightarrow \infty} P_t^h(\theta_{\phi h}^*(s, \cdot))(x) \leq \int_E \theta_{\phi h}^*(s, x) \tilde{m}(dx) \tag{6.6}$$

for all $x \in E$. We know from Lemma 5.2 that $\theta_{\phi h}^*(s, x)$ is bounded. and $\lim_{s \rightarrow \infty} \theta_{\phi h}^*(s, x) = 0$. Hence by (6.5), (6.6) and the bounded convergence theorem,

$$\begin{aligned} \limsup_{s \rightarrow \infty} \limsup_{t \rightarrow \infty} e^{\lambda_1(s+t)} \mathbb{P}_\mu \left(\langle \phi h, X_{s+t}^* + I_s^{*,t} \rangle \right) &\leq \limsup_{s \rightarrow \infty} \int_E \theta_{\phi h}^*(s, x) \tilde{m}(dx) \langle h, \mu \rangle \\ &\leq \int_E \limsup_{s \rightarrow \infty} \theta_{\phi h}^*(s, x) \tilde{m}(dx) \langle h, \mu \rangle = 0. \end{aligned}$$

□

Lemma 6.3. For any $\mu \in \mathcal{M}_c(E)$, $\phi \in \mathcal{B}_b^+(E)$ and $s > 0$,

$$\lim_{t \rightarrow \infty} e^{\lambda_1(s+t)} \left[\sum_{i=1}^{N_t} \langle \phi h, I_s^{i,t} \rangle - \sum_{i=1}^{N_t} \mathbb{P}_\mu \left(\langle \phi h, I_s^{i,t} \rangle | \mathcal{F}_t \right) \right] = 0 \quad \text{in } L^1(\mathbb{P}_\mu).$$

Proof. Fix $\phi \in \mathcal{B}_b^+(E)$. For $s, t > 0$, define

$$\begin{aligned} S_{s,t} &:= e^{\lambda_1(s+t)} \sum_{i=1}^{N_t} \langle \phi h, I_s^{i,t} \rangle, \\ \widehat{S}_{s,t} &:= e^{\lambda_1(s+t)} \sum_{i=1}^{N_t} \langle \phi h, I_s^{i,t} \rangle 1_{\{\langle \phi h, I_s^{i,t} \rangle < e^{-\lambda_1 t}\}}. \end{aligned}$$

Clearly by definition, $\widehat{S}_{s,t} \leq S_{s,t}$. Recall that given \mathcal{F}_t , $\{I^{i,t} : i = 1, \dots, N_t\}$ are independent and $I^{i,t}$ is equal in distribution to $(I; \mathbb{P}_{\cdot, \delta_{z_i(t)}})$. By this, we have

$$\begin{aligned} \mathbb{P}_\mu \left[\left(\widehat{S}_{s,t} - \mathbb{P}_\mu \left(\widehat{S}_{s,t} | \mathcal{F}_t \right) \right)^2 \right] &= \mathbb{P}_\mu \left[\text{Var} \left(\widehat{S}_{s,t} | \mathcal{F}_t \right) \right] \\ &\leq e^{2\lambda_1(s+t)} \mathbb{P}_\mu \left[\sum_{i=1}^{N_t} \mathbb{P}_\mu \left(\langle \phi h, I_s^{i,t} \rangle^2 1_{\{\langle \phi h, I_s^{i,t} \rangle < e^{-\lambda_1 t}\}} | \mathcal{F}_t \right) \right] \\ &= e^{2\lambda_1(s+t)} \mathbb{P}_\mu \left[\sum_{i=1}^{N_t} \mathbb{P}_{\cdot, \delta_{z_i(t)}} \left(\langle \phi h, I_s \rangle^2 1_{\{\langle \phi h, I_s \rangle < e^{-\lambda_1 t}\}} \right) \right]. \end{aligned} \quad (6.7)$$

Let $g_{s,t}(x) := w(x) \mathbb{P}_{\cdot, \delta_x} \left(\langle \phi h, I_s \rangle^2 1_{\{\langle \phi h, I_s \rangle < e^{-\lambda_1 t}\}} \right)$ for $x \in E$. Then by (5.6)

$$\begin{aligned} \text{RHS of (6.7)} &= e^{2\lambda_1(s+t)} \mathbb{P}_\mu \left(\left\langle \frac{g_{s,t}}{w}, Z_t \right\rangle \right) \\ &= e^{2\lambda_1(s+t)} \langle P_t^\beta(g_{s,t}), \mu \rangle \\ &= e^{\lambda_1(t+2s)} \langle P_t^h \left(\frac{g_{s,t}}{h} \right), h\mu \rangle. \end{aligned} \quad (6.8)$$

Clearly by (5.8),

$$g_{s,t}(x) \leq e^{-\lambda_1 t} w(x) \mathbb{P}_{\cdot, \delta_x} \left(\langle \phi h, I_s \rangle \right) = e^{-\lambda_1 t} \mathbb{P}_{\delta_x} \left(\langle \phi h, I_s \rangle \right) \leq e^{-\lambda_1 t} \mathbb{P}_{\delta_x} \left(\langle \phi h, X_s \rangle \right) \leq e^{-\lambda_1(s+t)} \|\phi\|_\infty h(x)$$

for all $x \in E$. For $x \in E$ and $t > 1$, by (3.6),

$$\begin{aligned} P_t^h \left(\frac{g_{s,t}}{h} \right) (x) &\leq \langle g_{s,t}, h \rangle + e^{-\lambda_h(t-1)} \tilde{a}_2(x)^{1/2} \|g_{s,t}\|_{L^2(E, m)} \\ &\leq \langle g_{s,t}, h \rangle + e^{-\lambda_h(t-1) - \lambda_1(s+t)} \|\phi\|_\infty \tilde{a}_2(x)^{1/2}. \end{aligned} \quad (6.9)$$

Hence by (6.7)-(6.9), we get

$$\mathbb{P}_\mu \left[\left(\widehat{S}_{s,t} - \mathbb{P}_\mu \left(\widehat{S}_{s,t} | \mathcal{F}_t \right) \right)^2 \right] \leq e^{\lambda_1(t+2s)} \langle h, \mu \rangle \langle g_{s,t}, h \rangle + e^{-\lambda_h(t-1) + \lambda_1 s} \|\phi\|_\infty \langle \tilde{a}_2^{-1/2} h, \mu \rangle. \quad (6.10)$$

Here $\langle \tilde{a}_2^{1/2} h, \mu \rangle = \int_E p^h(2, x, x)^{1/2} h(x) \mu(dx) < \infty$ since both $x \mapsto p^h(2, x, x)$ and h are bounded on the compact support of μ due to the continuity of $x \mapsto p^h(2, x, x)$ and h . Note that by Fubini's theorem

$$\begin{aligned}
& \int_1^\infty e^{\lambda_1 t} \langle g_{s,t}, h \rangle dt \\
&= \int_1^\infty e^{\lambda_1 t} dt \int_E h(x) w(x) m(dx) \int_{[0, e^{-\lambda_1 t})} y^2 \mathbb{P}_{\cdot, \delta_x} (\langle \phi h, I_s \rangle \in dy) \\
&= \int_E h(x) w(x) m(dx) \int_{e^{-\lambda_1}}^\infty \frac{1}{-\lambda_1 s^2} ds \int_{[0, s)} y^2 \mathbb{P}_{\cdot, \delta_x} (\langle \phi h, I_s \rangle \in dy) \\
&= \int_E h(x) w(x) m(dx) \int_{[0, \infty)} y^2 \mathbb{P}_{\cdot, \delta_x} (\langle \phi h, I_s \rangle \in dy) \int_{e^{-\lambda_1 \vee y}}^\infty \frac{1}{-\lambda_1 s^2} ds \\
&\leq \frac{1}{-\lambda_1} \int_E h(x) w(x) m(dx) \int_{[0, \infty)} y \mathbb{P}_{\cdot, \delta_x} (\langle \phi h, I_s \rangle \in dy) \\
&= \frac{1}{-\lambda_1} \int_E w(x) \mathbb{P}_{\cdot, \delta_x} (\langle \phi h, I_s \rangle) h(x) m(dx).
\end{aligned}$$

By (5.8) the integral in the right hand side equals

$$\begin{aligned}
\int_E \mathbb{P}_{\delta_x} (\langle \phi h, I_s \rangle) h(x) m(dx) &\leq \|\phi\|_\infty \int_E \mathbb{P}_{\delta_x} (\langle h, X_s \rangle) h(x) m(dx) \\
&= \|\phi\|_\infty e^{-\lambda_1 s} \int_E h(x)^2 m(dx) < \infty.
\end{aligned} \tag{6.11}$$

Hence we get $\limsup_{t \rightarrow \infty} e^{\lambda_1 t} \langle g_{s,t}, h \rangle = 0$. This together with (6.10) yields that

$$\limsup_{t \rightarrow \infty} \mathbb{P}_\mu \left[\left(\widehat{S}_{s,t} - \mathbb{P}_\mu \left(\widehat{S}_{s,t} | \mathcal{F}_t \right) \right)^2 \right] = 0,$$

and consequently

$$\lim_{t \rightarrow \infty} \left(\widehat{S}_{s,t} - \mathbb{P}_\mu \left(\widehat{S}_{s,t} | \mathcal{F}_t \right) \right) = 0 \quad \text{in } L^1(\mathbb{P}_\mu). \tag{6.12}$$

Recall that under \mathbb{P}_{δ_z} , Z_0 is a Poisson random measure with intensity $w(x) \delta_x(dy)$. Thus we have

$$\begin{aligned}
\mathbb{P}_{\delta_x} [\langle \phi h, I_s \rangle \mathbf{1}_{\{\langle \phi h, I_s \rangle \geq e^{-\lambda_1 t}\}}] &= \mathbb{P}_{\delta_x} \left[\sum_{i=1}^{N_0} \langle \phi h, I_s^{i,0} \rangle \mathbf{1}_{\{\sum_{i=1}^{N_0} \langle \phi h, I_s^{i,0} \rangle \geq e^{-\lambda_1 t}\}} \right] \\
&\geq \mathbb{P}_{\delta_x} \left[\sum_{i=1}^{N_0} \langle \phi h, I_s^{i,0} \rangle \mathbf{1}_{\{\langle \phi h, I_s^{i,0} \rangle \geq e^{-\lambda_1 t}\}} \right] \\
&= \mathbb{P}_{\delta_x} \left[\sum_{i=1}^{N_0} \mathbb{P}_{\cdot, \delta_{z_i(0)}} [\langle \phi h, I_s \rangle \mathbf{1}_{\{\langle \phi h, I_s \rangle \geq e^{-\lambda_1 t}\}}] \right] \\
&= w(x) \mathbb{P}_{\cdot, \delta_x} [\langle \phi h, I_s \rangle \mathbf{1}_{\{\langle \phi h, I_s \rangle \geq e^{-\lambda_1 t}\}}].
\end{aligned}$$

Using this and Markov property, we have

$$\begin{aligned}
\mathbb{P}_\mu \left(S_{s,t} - \widehat{S}_{s,t} \right) &= \mathbb{P}_\mu \left[\mathbb{P}_\mu (S_{s,t} | \mathcal{F}_t) - \mathbb{P}_\mu \left(\widehat{S}_{s,t} | \mathcal{F}_t \right) \right] \\
&= e^{\lambda_1(s+t)} \mathbb{P}_\mu \left[\sum_{i=1}^{N_t} \mathbb{P}_{\cdot, \delta_{z_i(t)}} (\langle \phi h, I_s \rangle \mathbf{1}_{\{\langle \phi h, I_s \rangle \geq e^{-\lambda_1 t}\}}) \right] \\
&\leq e^{\lambda_1(s+t)} \mathbb{P}_\mu \left[\sum_{i=1}^{N_t} w(z_i(t))^{-1} \mathbb{P}_{\delta_{z_i(t)}} (\langle \phi h, I_s \rangle \mathbf{1}_{\{\langle \phi h, I_s \rangle \geq e^{-\lambda_1 t}\}}) \right]
\end{aligned}$$

$$\begin{aligned}
&= e^{\lambda_1(s+t)} \mathbb{P}_\mu \left(\left\langle \frac{f_{s,t}}{w}, Z_t \right\rangle \right) \\
&= e^{\lambda_1(s+t)} \langle P_t^\beta f_{s,t}, \mu \rangle \\
&= e^{\lambda_1 s} \langle P_t^h \left(\frac{f_{s,t}}{h} \right), h\mu \rangle,
\end{aligned} \tag{6.13}$$

where $f_{s,t}(x) := \mathbb{P}_{\delta_x} (\langle \phi h, I_s \rangle 1_{\{\langle \phi h, I_s \rangle \geq e^{-\lambda_1 t}\}})$. We observe that $f_{s,t}(x) \leq \mathbb{P}_{\delta_x} (\langle \phi h, X_s \rangle) \leq \|\phi\|_\infty e^{-\lambda_1 s} h(x)$ for every $x \in E$. By (3.6) again, we get for $x \in E$ and $t > 1$,

$$\begin{aligned}
P_t^h \left(\frac{f_{s,t}}{h} \right) (x) &\leq \langle f_{s,t}, h \rangle + e^{-\lambda_h(t-1)} \tilde{a}_2(x)^{1/2} \|f_{s,t}\|_{L^2(E,m)} \\
&\leq \langle f_{s,t}, h \rangle + e^{-\lambda_h(t-1) - \lambda_1 s} \|\phi\|_\infty \tilde{a}_2(x)^{1/2}.
\end{aligned}$$

This together with (6.13) yields that for $t > 1$,

$$\begin{aligned}
\mathbb{P}_\mu \left(S_{s,t} - \widehat{S}_{s,t} \right) &= \mathbb{P}_\mu \left[\mathbb{P}_\mu (S_{s,t} | \mathcal{F}_t) - \mathbb{P}_\mu \left(\widehat{S}_{s,t} | \mathcal{F}_t \right) \right] \\
&\leq e^{\lambda_1 s} \langle h, \mu \rangle \langle f_{s,t}, h \rangle + e^{-\lambda_h(t-1)} \|\phi\|_\infty \langle \tilde{a}_2^{1/2} h, \mu \rangle.
\end{aligned} \tag{6.14}$$

It follows from Fubini's theorem and Lemma 6.1 that

$$\begin{aligned}
\int_0^\infty \langle f_{s,t}, h \rangle dt &= \int_0^\infty dt \int_E h(x) m(dx) \int_{[e^{-\lambda_1 t}, \infty)} y \mathbb{P}_{\delta_x} (\langle \phi h, I_s \rangle \in dy) \\
&= \int_E h(x) m(dx) \int_1^\infty \frac{1}{-\lambda_1 s} ds \int_{[s, \infty)} y \mathbb{P}_{\delta_x} (\langle \phi h, I_s \rangle \in dy) \\
&= \frac{1}{-\lambda_1} \int_E h(x) m(dx) \int_{[1, \infty)} y \mathbb{P}_{\delta_x} (\langle \phi h, I_s \rangle \in dy) \int_1^y \frac{1}{s} ds \\
&= \frac{1}{-\lambda_1} \int_E h(x) m(dx) \int_{[1, \infty)} y \log y \mathbb{P}_{\delta_x} (\langle \phi h, I_s \rangle \in dy) \\
&= \frac{1}{-\lambda_1} \int_E \mathbb{P}_{\delta_x} (\langle \phi h, I_s \rangle \log^+ \langle \phi h, I_s \rangle) h(x) m(dx) \\
&\leq \frac{1}{-\lambda_1} \int_E \mathbb{P}_{\delta_x} (\langle \phi h, X_s \rangle \log^+ \langle \phi h, X_s \rangle) h(x) m(dx) < \infty.
\end{aligned} \tag{6.15}$$

Immediately, $\lim_{t \rightarrow \infty} \langle f_{s,t}, h \rangle = 0$. Hence by (6.14) we get

$$\lim_{t \rightarrow \infty} \mathbb{P}_\mu \left(S_{s,t} - \widehat{S}_{s,t} \right) = \lim_{t \rightarrow \infty} \mathbb{P}_\mu \left[\mathbb{P}_\mu (S_{s,t} | \mathcal{F}_t) - \mathbb{P}_\mu \left(\widehat{S}_{s,t} | \mathcal{F}_t \right) \right] = 0.$$

In other words,

$$\lim_{t \rightarrow \infty} \left(S_{s,t} - \widehat{S}_{s,t} \right) = \lim_{t \rightarrow \infty} \left(\mathbb{P}_\mu (S_{s,t} | \mathcal{F}_t) - \mathbb{P}_\mu \left(\widehat{S}_{s,t} | \mathcal{F}_t \right) \right) = 0 \quad \text{in } L^1(\mathbb{P}_\mu). \tag{6.16}$$

Combining (6.12) and (6.16), we get $\lim_{t \rightarrow \infty} (S_{s,t} - \mathbb{P}_\mu (S_{s,t} | \mathcal{F}_t)) = 0$ in $L^1(\mathbb{P}_\mu)$. This completes the proof. \square

Lemma 6.4. For any $\mu \in \mathcal{M}_c(E)$ and $\phi \in \mathcal{B}_b^+(E)$,

$$\lim_{s \rightarrow \infty} \lim_{t \rightarrow \infty} e^{\lambda_1(s+t)} \sum_{i=1}^{N_t} \mathbb{P}_\mu (\langle \phi h, I_s^{i,t} \rangle | \mathcal{F}_t) = \langle \phi h, h \rangle W_\infty^h(X) \quad \text{in } L^1(\mathbb{P}_\mu). \tag{6.17}$$

Proof. In view of Theorem 2.11 and Theorem 2.9, under Assumptions 1-3 and Assumption 4(i), (6.17) is equivalent to

$$\lim_{s \rightarrow \infty} \lim_{t \rightarrow \infty} \left[e^{\lambda_1(s+t)} \sum_{i=1}^{N_t} \mathbb{P}_\mu (\langle \phi h, I_s^{i,t} \rangle | \mathcal{F}_t) - \langle \phi h, h \rangle W_t^{h/w}(Z) \right] = 0 \quad \text{in } L^1(\mathbb{P}_\mu). \tag{6.18}$$

Fix $\mu \in \mathcal{M}_c(E)$ and $\phi \in \mathcal{B}_b^+(E)$. Note that for $x \in E$ and $s > 0$,

$$\begin{aligned}\mathbb{P}_{\delta_x}(\langle \phi h, I_s \rangle) &= \mathbb{P}_{\delta_x}(\langle \phi h, X_s \rangle) - \mathbb{P}_{\delta_x}(\langle \phi h, X_s^* \rangle) \\ &= P_s^\beta(\phi h)(x) - P_s^{\beta^*}(\phi h)(x).\end{aligned}$$

By this and Markov property, we have

$$\begin{aligned}e^{\lambda_1(s+t)} \sum_{i=1}^{N_t} \mathbb{P}_\mu(\langle \phi h, I_s^{i,t} \rangle | \mathcal{F}_t) &= e^{\lambda_1(s+t)} \sum_{i=1}^{N_t} \mathbb{P}_{\cdot, \delta_{z_i(t)}}(\langle \phi h, I_s \rangle) \\ &= e^{\lambda_1(s+t)} \sum_{i=1}^{N_t} w(z_i(t))^{-1} \mathbb{P}_{\delta_{z_i(t)}}(\langle \phi h, I_s \rangle) \\ &= e^{\lambda_1(s+t)} \left\langle \frac{1}{w} (P_s^\beta(\phi h) - P_s^{\beta^*}(\phi h)), Z_t \right\rangle \\ &= e^{\lambda_1 t} \left\langle \frac{h}{w} (P_s^h \phi - \theta_{\phi h}^*(s, \cdot)), Z_t \right\rangle.\end{aligned}\tag{6.19}$$

Let $g(s, x) := \left| P_s^h \phi(x) - \theta_{\phi h}^*(s, x) - \langle \phi h, h \rangle \right|$ for $s > 0$ and $x \in E$. Clearly g is bounded from above by $3\|\phi\|_\infty$. By (6.19),

$$\begin{aligned}I(s, t) &:= \mathbb{P}_\mu \left[\left| e^{\lambda_1(s+t)} \sum_{i=1}^{N_t} \mathbb{P}_\mu(\langle \phi h, I_s^{i,t} \rangle | \mathcal{F}_t) - \langle \phi h, h \rangle W_t^{h/w}(Z) \right| \right] \\ &= e^{\lambda_1 t} \mathbb{P}_\mu \left(\left| \left\langle \frac{h}{w} (P_s^h \phi - \theta_{\phi h}^*(s, \cdot)) - \langle \phi h, h \rangle, Z_t \right\rangle \right| \right) \\ &\leq e^{\lambda_1 t} \mathbb{P}_\mu \left(\left\langle \frac{h}{w} g(s, \cdot), Z_t \right\rangle \right) \\ &= e^{\lambda_1 t} \langle P_t^\beta(hg(s, \cdot)), \mu \rangle \\ &= \langle P_t^h(g(s, \cdot)), h\mu \rangle.\end{aligned}\tag{6.20}$$

Since by (3.6), for $t > 1$ and $x \in E$,

$$\begin{aligned}P_t^h(g(s, \cdot))(x) &\leq \langle g(s, \cdot), h^2 \rangle + e^{-\lambda_h(t-1)} \tilde{a}_2(x)^{1/2} \|g(s, \cdot)\|_{L^2(E, \tilde{m})} \\ &\leq \langle g(s, \cdot), h^2 \rangle + 3e^{-\lambda_h(t-1)} \|\phi\|_\infty \tilde{a}_2(x)^{1/2},\end{aligned}$$

it follows by (6.20) that $I(s, t) \leq \langle g(s, \cdot), h^2 \rangle \langle h, \mu \rangle + 3e^{-\lambda_h(t-1)} \|\phi\|_\infty \langle \tilde{a}_2^{1/2} h, \mu \rangle$. Hence we get

$$\limsup_{t \rightarrow \infty} I(s, t) \leq \langle g(s, \cdot), h^2 \rangle \langle h, \mu \rangle.\tag{6.21}$$

Furthermore, by (3.6) and Lemma 5.2, for $s > 1$ and $x \in E$,

$$\begin{aligned}g(s, x) &\leq \left| P_s^h \phi - \langle \phi h, h \rangle \right| + \theta_{\phi h}^*(s, x) \\ &\leq e^{-\lambda_h(t-1)} \tilde{a}_2(x)^{1/2} \|\phi\|_{L^2(E, \tilde{m})} + \theta_{\phi h}^*(s, x) \rightarrow 0 \text{ as } s \rightarrow \infty.\end{aligned}$$

Thus $\lim_{s \rightarrow \infty} \langle g(s, \cdot), h^2 \rangle = 0$ by the bounded convergence theorem. This and (6.21) yields that $\lim_{s \rightarrow \infty} \lim_{t \rightarrow \infty} I(s, t) = 0$. Hence we prove (6.18). \square

Proof of Theorem 2.12: We know by [16, Lemma 3.2] that if for any $\mu \in \mathcal{M}_c(E)$ and $f \in \mathcal{B}^+(E)$ with f/h bounded,

$$\lim_{t \rightarrow \infty} e^{\lambda_1 t} \langle f, X_t \rangle = \langle f, h \rangle W_\infty^h(X) \quad \text{in } L^1(\mathbb{P}_\mu),\tag{6.22}$$

then the convergence in (6.22) holds for any $\mu \in \mathcal{M}_F^h(E)$. Henceforth we assume $\mu \in \mathcal{M}_c(E)$. We consider the skeleton space for convenience. For an arbitrary $f \in \mathcal{B}^+(E)$ with f/h bounded, let $\phi(x) := f(x)/h(x) \in \mathcal{B}_b^+(E)$. For any $s, t > 0$, under \mathbb{P}_μ ,

$$e^{\lambda_1(s+t)} \langle f, X_{s+t} \rangle - \langle f, h \rangle W_\infty^h(X)$$

$$\begin{aligned}
&= e^{\lambda_1(s+t)} \langle \phi h, X_{s+t}^* + I_s^{*,t} \rangle + \left[e^{\lambda_1(s+t)} \sum_{i=1}^{N_t} \langle \phi h, I_s^{i,t} \rangle - e^{\lambda_1(s+t)} \sum_{i=1}^{N_t} \mathbb{P}_\mu (\langle \phi h, I_s^{i,t} \rangle | \mathcal{F}_t) \right] \\
&\quad + \left[e^{\lambda_1(s+t)} \sum_{i=1}^{N_t} \mathbb{P}_\mu (\langle \phi h, I_s^{i,t} \rangle | \mathcal{F}_t) - \langle \phi h, h \rangle W_\infty^h(X) \right].
\end{aligned}$$

Thus by letting $t \rightarrow \infty$ and $s \rightarrow \infty$, (6.22) follows immediately from Lemma 6.2, Lemma 6.3 and Lemma 6.4. \square

Proposition 6.5. *Under Assumptions 1-3 and Assumption 4(i), Assumption 5' is equivalent to Assumption 5.*

Proof. Clearly by the symmetry of P_t^B , Assumption 5 implies Assumption 5'. So we only need to show that Assumption 5' is sufficient for Assumption 5. For $f \in \mathcal{B}^+(E)$ with fw/h bounded, let $\phi := fw/h \in \mathcal{B}_b^+(E)$. Then for any $\mu \in \mathcal{M}_c(E)$, $\sigma > 0$ and $m, n \in \mathbb{N}$,

$$\begin{aligned}
&e^{\lambda_1(m+n)\sigma} \langle f, Z_{(m+n)\sigma} \rangle - \langle f, wh \rangle W_\infty^{h/w}(Z) \\
&= e^{\lambda_1(m+n)\sigma} \langle \frac{h}{w} \phi, Z_{(m+n)\sigma} \rangle - \langle \phi, h^2 \rangle W_\infty^{h/w}(Z) \\
&= \left[e^{\lambda_1(m+n)\sigma} \langle \frac{h}{w} \phi, Z_{(m+n)\sigma} \rangle - e^{\lambda_1(m+n)\sigma} \mathbb{P}_\mu \left(\langle \frac{h}{w} \phi, Z_{(m+n)\sigma} \rangle | \mathcal{F}_{n\sigma} \right) \right] \\
&\quad + \left[e^{\lambda_1(m+n)\sigma} \mathbb{P}_\mu \left(\langle \frac{h}{w} \phi, Z_{(m+n)\sigma} \rangle | \mathcal{F}_{n\sigma} \right) - \langle \phi, h^2 \rangle W_\infty^{h/w}(Z) \right] \\
&=: I(m, n) + II(m, n).
\end{aligned}$$

Note that by the Markov property of Z , $e^{\lambda_1(m+n)\sigma} \mathbb{P}_\mu (\langle \frac{h}{w} \phi, Z_{(m+n)\sigma} \rangle | \mathcal{F}_{n\sigma}) = e^{\lambda_1(m+n)\sigma} \mathbb{P}_{\cdot, Z_{n\sigma}} (\langle \frac{h}{w} \phi, Z_{m\sigma} \rangle) = e^{\lambda_1(m+n)\sigma} \langle \frac{1}{w} P_{m\sigma}^\beta(h\phi), Z_{n\sigma} \rangle = e^{\lambda_1 n\sigma} \langle \frac{h}{w} P_{m\sigma}^h(\phi), Z_{n\sigma} \rangle$. Thus Assumption 5' implies that $II(m, n)$ converges to 0 almost surely for some $m \in \mathbb{N}$. Hence the proof is finished if we can show that for any $m \in \mathbb{N}$,

$$\lim_{n \rightarrow \infty} I(m, n) = 0 \quad \mathbb{P}_\mu\text{-a.s.} \quad (6.23)$$

It follows from Theorem 2.11, Lemma 6.1 and the fact that $\log^+ ab \leq \log^+ a + \log^+ b$ for all $a, b \geq 0$ that under Assumptions 1-3 and Assumption 4(i),

$$\int_E \mathbb{P}_{\delta_x} \left(\langle \frac{h}{w} \phi, Z_t \rangle \log^+ \langle \frac{h}{w} \phi, Z_t \rangle \right) h(x) m(dx) < \infty \quad (6.24)$$

for all $t > 0$. Recall that under \mathbb{P}_{δ_x} , N_0 is a random variable with mean $w(x)$. By this we have

$$\begin{aligned}
\mathbb{P}_{\delta_x} \left(\langle \frac{h}{w} \phi, Z_t \rangle \log^+ \langle \frac{h}{w} \phi, Z_t \rangle \right) &= \mathbb{P}_{\delta_x} \left(\sum_{i=1}^{N_0} \langle \frac{h}{w} \phi, Z_t^{i,0} \rangle \log^+ \langle \frac{h}{w} \phi, \sum_{i=1}^{N_0} Z_t^{i,0} \rangle \right) \\
&\geq \mathbb{P}_{\delta_x} \left(\sum_{i=1}^{N_0} \langle \frac{h}{w} \phi, Z_t^{i,0} \rangle \log^+ \langle \frac{h}{w} \phi, Z_t^{i,0} \rangle \right) \\
&= \mathbb{P}_{\delta_x} \left(N_0 \mathbb{P}_{\cdot, \delta_x} \left(\langle \frac{h}{w} \phi, Z_t \rangle \log^+ \langle \frac{h}{w} \phi, Z_t \rangle \right) \right) \\
&= w(x) \mathbb{P}_{\cdot, \delta_x} \left(\langle \frac{h}{w} \phi, Z_t \rangle \log^+ \langle \frac{h}{w} \phi, Z_t \rangle \right).
\end{aligned}$$

Thus (6.24) implies that

$$\int_E \mathbb{P}_{\cdot, \delta_x} \left(\langle \frac{h}{w} \phi, Z_t \rangle \log^+ \langle \frac{h}{w} \phi, Z_t \rangle \right) w(x) h(x) m(dx) < \infty \quad (6.25)$$

Recall that the skeleton Z is a supercritical branching Markov process with spatial motion ξ^w which is symmetric with respect to the measure $w^2 m$. (6.23) follows from (6.25) (instead of [10, (5.1)]) and Borel-Cantelli lemma in the same way as [10, Lemma 5.2]. We omit the details here. \square

7 Strong law of large numbers

To prove the strong law of large numbers, we know by [8] that it suffices to consider fixed test functions.

Lemma 7.1. [Chen et al. [8]] *Suppose Assumption 2 holds. If for any $\mu \in \mathcal{M}_F^h(E)$ and $\phi \in C_0^+(E)$,*

$$\lim_{t \rightarrow \infty} e^{\lambda_1 t} \langle \phi h, X_t \rangle = \langle \phi h, h \rangle W_\infty^h(X) \quad \mathbb{P}_\mu\text{-a.s.} \quad (7.1)$$

then there exists $\Omega_0 \subset \Omega$ of \mathbb{P}_μ -full probability for every $\mu \in \mathcal{M}_F^h(E)$ such that on Ω_0 , for every m -almost everywhere continuous nonnegative measurable function f with f/h bounded,

$$\lim_{t \rightarrow \infty} e^{\lambda_1 t} \langle f, X_t \rangle = \langle f, h \rangle W_\infty^h(X).$$

Lemma 7.2. *Suppose Assumption 2 holds. If (7.1) holds for any $\mu \in \mathcal{M}_c(E)$ and $\phi \in C_0^+(E)$, it holds for any $\mu \in \mathcal{M}_F^h(E)$.*

Proof. The main idea of this proof is borrowed from [16, Lemma 3.2(i)]. Fix $\mu \in \mathcal{M}_F^h(E)$. Take a sequence of sets $\{B_k : k \in \mathbb{N}\}$ such that $B_0 = \emptyset$, $B_k \Subset E$, $B_k \subset B_{k+1}$ and $\bigcup_{k=1}^\infty B_k = E$. Let $\widehat{B}_k := B_k \setminus B_{k-1}$. On a suitable probability space with probability measure \mathbb{P}_μ , let $\{X^{\widehat{B}_k} : k \in \mathbb{N}\}$ be independent (P_t, ψ_β) -superprocesses where $X^{\widehat{B}_k}$ is started in $1_{\widehat{B}_k} \mu$. Then by the branching property, $X^{B_k} := \sum_{i=1}^k X^{\widehat{B}_i}$, $X^{E \setminus B_k} := \sum_{i=k+1}^\infty X^{\widehat{B}_i}$ and $X := X^{B_k} + X^{E \setminus B_k}$ are (P_t, ψ_β) -superprocesses started in $1_{B_k} \mu$, $1_{E \setminus B_k} \mu$ and μ respectively. In particular, $W_t^h(X) = W_t^h(X^{B_k}) + W_t^h(X^{E \setminus B_k})$ and the martingale limits $W_\infty^h(X^{E \setminus B_k}) = \lim_{t \rightarrow \infty} W_t^h(X^{E \setminus B_k})$ is non-increasing in k . Since $\mu \in \mathcal{M}_F^h(E)$, by Fatou's lemma

$$\mathbb{P}_\mu \left(W_\infty^h(X^{E \setminus B_k}) \right) \leq \liminf_{t \rightarrow \infty} \mathbb{P}_\mu \left(W_t^h(X^{E \setminus B_k}) \right) = \langle h, 1_{E \setminus B_k} \mu \rangle \rightarrow 0 \quad \text{as } k \rightarrow \infty.$$

Thus $\lim_{k \rightarrow \infty} W_\infty^h(X^{E \setminus B_k}) = 0$ in $L^1(\mathbb{P}_\mu)$ and hence \mathbb{P}_μ -a.s. by the monotonicity.

For any $\phi \in C_0^+(E)$,

$$\begin{aligned} & \left| e^{\lambda_1 t} \langle \phi h, X_t \rangle - \langle \phi h, h \rangle W_\infty^h(X) \right| \\ & \leq \left| e^{\lambda_1 t} \langle \phi h, X_t^{B_k} \rangle - \langle \phi h, h \rangle W_\infty^h(X^{B_k}) \right| + e^{\lambda_1 t} \langle \phi h, X_t^{E \setminus B_k} \rangle + \langle \phi h, h \rangle W_\infty^h(X^{E \setminus B_k}) \\ & \leq \left| e^{\lambda_1 t} \langle \phi h, X_t^{B_k} \rangle - \langle \phi h, h \rangle W_\infty^h(X^{B_k}) \right| + \|\phi\|_\infty W_t^h(X^{E \setminus B_k}) + \langle \phi h, h \rangle W_\infty^h(X^{E \setminus B_k}). \end{aligned}$$

Since $1_{B_k} \mu \in \mathcal{M}_c(E)$, the first term converges to 0 as $t \rightarrow +\infty$ by our assumption. Therefore we get (7.1) for $\mu \in \mathcal{M}_F^h(E)$ by first letting $t \rightarrow \infty$ and then $k \rightarrow \infty$. \square

7.1 Strong law of large numbers along lattice times

Lemma 7.3. *Suppose Assumptions 1-3 and Assumption 4(i) hold. Then for any $\mu \in \mathcal{M}_c(E)$, $\phi \in \mathcal{B}_b^+(E)$, $\sigma > 0$ and $m \in \mathbb{N}$,*

$$\lim_{n \rightarrow \infty} e^{\lambda_1(m+n)\sigma} \left[\sum_{i=1}^{N_{n\sigma}} \langle \phi h, I_{m\sigma}^{i,n\sigma} \rangle - \sum_{i=1}^{N_{n\sigma}} \mathbb{P}_\mu \left(\langle \phi h, I_{m\sigma}^{i,n\sigma} \rangle | \mathcal{F}_{n\sigma} \right) \right] = 0 \quad \mathbb{P}_\mu\text{-a.s.}$$

Proof. In this proof, we adopt the same notation as defined in the proof of Lemma 6.3. For $m, n \in \mathbb{N}$, let

$$S_{m\sigma, n\sigma} := e^{\lambda_1(m+n)\sigma} \sum_{i=1}^{N_{n\sigma}} \langle \phi h, I_{m\sigma}^{i,n\sigma} \rangle,$$

$$\widehat{S}_{m\sigma, n\sigma} := e^{\lambda_1(m+n)\sigma} \sum_{i=1}^{N_{n\sigma}} \langle \phi h, I_{m\sigma}^{i,n\sigma} \rangle 1_{\{\langle \phi h, I_{m\sigma}^{i,n\sigma} \rangle < e^{-\lambda_1 n\sigma}\}}.$$

We have proved in (6.10) that for $n\sigma > 1$,

$$\begin{aligned} \mathbb{P}_\mu \left[\left(\widehat{S}_{m\sigma, n\sigma} - \mathbb{P}_\mu \left(\widehat{S}_{m\sigma, n\sigma} | \mathcal{F}_{n\sigma} \right) \right)^2 \right] &\leq e^{\lambda_1(n\sigma+2m\sigma)} \langle g_{m\sigma, n\sigma}, h \rangle \langle h, \mu \rangle \\ &\quad + e^{-\lambda_h(n\sigma-1)+\lambda_1 m\sigma} \|\phi\|_\infty \widetilde{a}_2^{1/2} h, \mu \end{aligned} \quad (7.2)$$

where $g_{m\sigma, n\sigma}(x) := w(x) \mathbb{P}_{\cdot, \delta_x} (\langle \phi h, I_{m\sigma} \rangle^2 1_{\{\langle \phi h, I_{m\sigma} \rangle < e^{-\lambda_1 n\sigma}\}})$ for $x \in E$. Note that by (6.11)

$$\begin{aligned} \sum_{n=1}^{\infty} e^{\lambda_1 n\sigma} \langle g_{m\sigma, n\sigma}, h \rangle &= \sum_{n=1}^{\infty} e^{\lambda_1 n\sigma} \int_E h(x) w(x) \mathbb{P}_{\cdot, \delta_x} (\langle \phi h, I_{m\sigma} \rangle^2 1_{\{\langle \phi h, I_{m\sigma} \rangle < e^{-\lambda_1 n\sigma}\}}) m(dx) \\ &\leq \int_1^{\infty} e^{\lambda_1 \sigma(s-1)} \int_E h(x) w(x) \mathbb{P}_{\cdot, \delta_x} (\langle \phi h, I_{m\sigma} \rangle^2 1_{\{\langle \phi h, I_{m\sigma} \rangle < e^{-\lambda_1 s\sigma}\}}) m(dx) \\ &= e^{-\lambda_1 \sigma} \int_1^{\infty} e^{\lambda_1 s\sigma} \langle g_{m\sigma, s\sigma}, h \rangle ds < \infty. \end{aligned}$$

This together with (7.2) yields that $\sum_{n=1}^{\infty} \mathbb{P}_\mu \left[\left(\widehat{S}_{m\sigma, n\sigma} - \mathbb{P}_\mu \left(\widehat{S}_{m\sigma, n\sigma} | \mathcal{F}_{n\sigma} \right) \right)^2 \right] < \infty$. Thus by Borel-Cantelli lemma,

$$\lim_{n \rightarrow \infty} \left(\widehat{S}_{m\sigma, n\sigma} - \mathbb{P}_\mu \left(\widehat{S}_{m\sigma, n\sigma} | \mathcal{F}_{n\sigma} \right) \right) = 0 \quad \mathbb{P}_\mu\text{-a.s.} \quad (7.3)$$

Similarly, we have proved in (6.14) that for $n\sigma > 1$,

$$\begin{aligned} \mathbb{P}_\mu \left(S_{m\sigma, n\sigma} - \widehat{S}_{m\sigma, n\sigma} \right) &= \mathbb{P}_\mu \left[\mathbb{P}_\mu \left(S_{m\sigma, n\sigma} | \mathcal{F}_{n\sigma} \right) - \mathbb{P}_\mu \left(\widehat{S}_{m\sigma, n\sigma} | \mathcal{F}_{n\sigma} \right) \right] \\ &\leq e^{\lambda_1 m\sigma} \langle f_{m\sigma, n\sigma}, h \rangle \langle h, \mu \rangle + e^{-\lambda_h(n\sigma-1)} \|\phi\|_\infty \widetilde{a}_2^{1/2} h, \mu, \end{aligned} \quad (7.4)$$

where $f_{m\sigma, n\sigma}(x) := \mathbb{P}_{\delta_x} (\langle \phi h, I_{m\sigma} \rangle 1_{\{\langle \phi h, I_{m\sigma} \rangle \geq e^{-\lambda_1 n\sigma}\}})$. Note that by (6.15),

$$\begin{aligned} \sum_{n=1}^{\infty} \langle f_{m\sigma, n\sigma}, h \rangle &= \sum_{n=1}^{\infty} \int_E h(x) \mathbb{P}_{\delta_x} (\langle \phi h, I_{m\sigma} \rangle 1_{\{\langle \phi h, I_{m\sigma} \rangle \geq e^{-\lambda_1 n\sigma}\}}) m(dx) \\ &\leq \int_0^{\infty} ds \int_E h(x) \mathbb{P}_{\delta_x} (\langle \phi h, I_{m\sigma} \rangle 1_{\{\langle \phi h, I_{m\sigma} \rangle \geq e^{-\lambda_1 s\sigma}\}}) m(dx) \\ &= \int_0^{\infty} \langle f_{m\sigma, s\sigma}, h \rangle ds < \infty. \end{aligned} \quad (7.5)$$

Hence by (7.4) and (7.5),

$$\sum_{n=1}^{\infty} \mathbb{P}_\mu \left(S_{m\sigma, n\sigma} - \widehat{S}_{m\sigma, n\sigma} \right) = \mathbb{P}_\mu \left[\mathbb{P}_\mu \left(S_{m\sigma, n\sigma} | \mathcal{F}_{n\sigma} \right) - \mathbb{P}_\mu \left(\widehat{S}_{m\sigma, n\sigma} | \mathcal{F}_{n\sigma} \right) \right] < \infty.$$

It follows by Borel-Cantelli lemma that

$$\lim_{n \rightarrow \infty} \left(S_{m\sigma, n\sigma} - \widehat{S}_{m\sigma, n\sigma} \right) = \lim_{n \rightarrow \infty} \left(\mathbb{P}_\mu \left(S_{m\sigma, n\sigma} | \mathcal{F}_{n\sigma} \right) - \mathbb{P}_\mu \left(\widehat{S}_{m\sigma, n\sigma} | \mathcal{F}_{n\sigma} \right) \right) = 0 \quad \mathbb{P}_\mu\text{-a.s.}$$

This together with (7.3) yield that $\lim_{n \rightarrow \infty} (S_{m\sigma, n\sigma} - \mathbb{P}_\mu (S_{m\sigma, n\sigma} | \mathcal{F}_{n\sigma})) = 0$ \mathbb{P}_μ -a.s. \square

Lemma 7.4. *Suppose Assumptions 1-3 and Assumption 5 hold. Then for any $\mu \in \mathcal{M}_c(E)$, $\sigma > 0$ and $\phi \in \mathcal{B}_b^+(E)$,*

$$\lim_{m \rightarrow \infty} \lim_{n \rightarrow \infty} e^{\lambda_1(m+n)\sigma} \sum_{i=1}^{N_{n\sigma}} \mathbb{P}_\mu (\langle \phi h, I_{m\sigma}^{i, n\sigma} \rangle | \mathcal{F}_{n\sigma}) = \langle \phi h, h \rangle W_\infty^h(X) \quad \mathbb{P}_\mu\text{-a.s.}$$

Proof. For $m, n \in \mathbb{N}$ and $\sigma > 0$, let $I(m, n) := e^{\lambda_1(m+n)\sigma} \sum_{i=1}^{N_{n\sigma}} \mathbb{P}_\mu (\langle \phi h, I_{m\sigma}^{i, n\sigma} \rangle | \mathcal{F}_{n\sigma})$. Then we have that (see, (6.19) in the proof of Lemma 6.4)

$$I(m, n) = e^{\lambda_1 n \sigma} \left\langle \frac{h}{w} P_{m\sigma}^h \phi, Z_{n\sigma} \right\rangle - e^{\lambda_1 n \sigma} \left\langle \frac{h}{w} \theta_{\phi h}^*(m\sigma, \cdot), Z_{n\sigma} \right\rangle.$$

Since $P_{m\sigma}^h \phi, \theta_{\phi h}^*(m\sigma, \cdot) \in \mathcal{B}_b^+(E)$, it follows by Assumption 5 that

$$\lim_{n \rightarrow \infty} I(m, n) = \langle P_{m\sigma}^h \phi, h^2 \rangle W_\infty^{h/w}(Z) - \langle \theta_{\phi h}^*(m\sigma, \cdot), h^2 \rangle W_\infty^{h/w}(Z) \quad \mathbb{P}_\mu\text{-a.s.} \quad (7.6)$$

Recall that $h^2 m$ is the invariant probability measure for $(\xi^h; \Pi^h)$. We have $\langle P_{m\sigma}^h \phi, h^2 \rangle = \langle \phi h, h \rangle$. Moreover by Lemma 5.2 and the bounded convergence theorem, $\lim_{m \rightarrow \infty} \langle \theta_{\phi h}^*(m\sigma, \cdot), h^2 \rangle = 0$. Therefore by Theorem 2.11 and (7.6)

$$\lim_{m \rightarrow \infty} \lim_{n \rightarrow \infty} I(m, n) = \langle \phi h, h \rangle W_\infty^{h/w}(Z) = \langle \phi h, h \rangle W_\infty^h(X) \quad \mathbb{P}_\mu\text{-a.s.}$$

□

Lemma 7.5. *Suppose Assumptions 1-3, 4(i) and 5 hold. Then for any $\mu \in \mathcal{M}_c(E)$, $\sigma > 0$ and $\phi \in \mathcal{B}_b^+(E)$,*

$$\lim_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \langle \phi h, X_{n\sigma} \rangle = \langle \phi h, h \rangle W_\infty^h(X) \quad \mathbb{P}_\mu\text{-a.s.}$$

Proof. Note that for any $m, n \in \mathbb{N}$, $\sigma > 0$ and $\phi \in \mathcal{B}_b^+(E)$,

$$\begin{aligned} & e^{\lambda_1(m+n)\sigma} \langle \phi h, X_{(m+n)\sigma} \rangle \\ \geq & e^{\lambda_1(m+n)\sigma} \sum_{i=1}^{N_{n\sigma}} \langle \phi h, I_{m\sigma}^{i, n\sigma} \rangle \\ = & e^{\lambda_1(m+n)\sigma} \sum_{i=1}^{N_{n\sigma}} \langle \phi h, I_{m\sigma}^{i, n\sigma} \rangle - e^{\lambda_1(m+n)\sigma} \sum_{i=1}^{N_{n\sigma}} \mathbb{P}_\mu (\langle \phi h, I_{m\sigma}^{i, n\sigma} \rangle | \mathcal{F}_{n\sigma}) + e^{\lambda_1(m+n)\sigma} \sum_{i=1}^{N_{n\sigma}} \mathbb{P}_\mu (\langle \phi h, I_{m\sigma}^{i, n\sigma} \rangle | \mathcal{F}_{n\sigma}). \end{aligned}$$

Then by Lemma 7.3 and Lemma 7.4, we have

$$\liminf_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \langle \phi h, X_{n\sigma} \rangle \geq \langle \phi h, h \rangle W_\infty^h(X) \quad \mathbb{P}_\mu\text{-a.s.}$$

Let $c := \|\phi\|_\infty$. Since $(c - \phi) \in \mathcal{B}_b^+(E)$, the same argument can be applied to $c - \phi$, and we conclude that under \mathbb{P}_μ ,

$$\begin{aligned} \limsup_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \langle \phi h, X_{n\sigma} \rangle &= \limsup_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \langle ch - (c - \phi)h, X_{n\sigma} \rangle \\ &= cW_\infty^h(X) - \liminf_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \langle (c - \phi)h, X_{n\sigma} \rangle \\ &\leq cW_\infty^h(X) - \langle (c - \phi)h, h \rangle W_\infty^h(X) = \langle \phi h, h \rangle W_\infty^h(X). \end{aligned}$$

Hence we complete the proof. □

7.2 From lattice times to continuous time

In this section we extend the convergence along lattice times in Lemma 7.5 to convergence along continuous time and then prove Theorem 2.13. Let $\{U^\kappa; \kappa > 0\}$ be the resolvent of the semigroup $\{P_t^h; t \geq 0\}$, that is,

$$U^\kappa f(x) := \int_0^\infty e^{-\kappa t} P_t^h f(x) dt \quad \text{for } x \in E \text{ and } f \in \mathcal{B}_b^+(E).$$

Under Assumption 6, for every $f \in C_0(E)$, by the dominated convergence theorem,

$$\|\kappa U^\kappa f - f\|_\infty \leq \int_0^\infty \kappa e^{-\kappa t} \|P_t^h f - f\|_\infty dt = \int_0^\infty e^{-s} \|P_{s/\kappa}^h f - f\|_\infty ds \rightarrow 0 \text{ as } \kappa \rightarrow \infty. \quad (7.7)$$

Lemma 7.6. *Suppose Assumptions 1-5 hold. Then for any $\mu \in \mathcal{M}_c(E)$, $\kappa > 0$ and $\phi \in \mathcal{B}_b^+(E)$,*

$$\lim_{t \rightarrow \infty} e^{\lambda_1 t} \langle (\kappa U^\kappa \phi)h, X_t \rangle = \langle \phi h, h \rangle W_\infty^h(X) \quad \mathbb{P}_\mu\text{-a.s.}$$

Proof. The idea of this proof is similar to that of [16, Proposition 3.14]. The main difference is that here we use the L^1 -convergence instead of the L^p -convergence used there. We consider in the skeleton space for convenience. Since $\kappa U^\kappa 1 = 1$ and $\kappa U^\kappa \phi \in \mathcal{B}_b^+(E)$, the same argument that led to Lemma 7.5 can be applied here and it suffices to prove that

$$\liminf_{t \rightarrow \infty} e^{\lambda_1 t} \langle (\kappa U^\kappa \phi)h, X_t \rangle \geq \langle \phi h, h \rangle W_\infty^h(X) \quad \mathbb{P}_\mu\text{-a.s.} \quad (7.8)$$

Fix $\mu \in \mathcal{M}_c(E)$ and $\phi \in \mathcal{B}_b^+(E)$. Let $g(x) := \kappa U^\kappa \phi(x)$ and $g_B(x) := g(x)1_B(x)$ with $B \Subset E$. Note that $\langle (\kappa U^\kappa \phi)h, h \rangle = \langle \phi h, h \rangle$ since $h^2 m$ is the invariant probability measure for $(\xi^h; \Pi^h)$. If we can show that

$$\liminf_{t \rightarrow \infty} e^{\lambda_1 t} \langle gh, X_t \rangle \geq \langle g_B h, h \rangle W_\infty^h(X) \quad \mathbb{P}_\mu\text{-a.s.} \quad (7.9)$$

for any $B \Subset E$, then choose an increasing sequence $B_n \Subset E$ with $\bigcup_{n=1}^\infty B_n = E$, (7.8) follows from the monotone convergence theorem. Suppose $\sigma > 0$. For any $t \in [n\sigma, (n+1)\sigma]$,

$$\begin{aligned} & e^{\lambda_1 t} \langle gh, X_t \rangle - \langle g_B h, h \rangle W_\infty^h(X) \\ \geq & \left[e^{\lambda_1 t} \langle gh, X_t \rangle - e^{\lambda_1 (n+1)\sigma} \mathbb{P}_\mu \left(\langle gh, X_{(n+1)\sigma} \rangle | \mathcal{F}_t \right) \right] \\ + & \left[e^{\lambda_1 (n+1)\sigma} \mathbb{P}_\mu \left(\langle g_B h, X_{(n+1)\sigma} \rangle | \mathcal{F}_t \right) - e^{\lambda_1 (n+1)\sigma} \mathbb{P}_\mu \left(\langle g_B h, X_{(n+1)\sigma} \rangle | \mathcal{F}_{n\sigma} \right) \right] \\ + & \left[e^{\lambda_1 (n+1)\sigma} \mathbb{P}_\mu \left(\langle g_B h, X_{(n+1)\sigma} \rangle | \mathcal{F}_{n\sigma} \right) - \langle g_B h, h \rangle W_\infty^h(X) \right] \\ =: & \theta_{1,g}(n, \sigma, t) + \theta_{2,g_B}(n, \sigma, t) + \theta_{3,g_B}(n, \sigma). \end{aligned}$$

To prove (7.9), it suffices to prove that under \mathbb{P}_μ ,

- (1) $\limsup_{\sigma \rightarrow 0} \limsup_{n \rightarrow \infty} \sup_{t \in [n\sigma, (n+1)\sigma]} |\theta_{1,g}(n, \sigma, t)| = 0.$
- (2) $\limsup_{n \rightarrow \infty} \sup_{t \in [n\sigma, (n+1)\sigma]} |\theta_{2,g_B}(n, \sigma, t)| = 0.$
- (3) $\lim_{n \rightarrow \infty} |\theta_{3,g_B}(n, \sigma)| = 0.$

We begin with the proof of (1). By the Markov property of X , we have

$$\begin{aligned} \theta_{1,g}(n, \sigma, t) &= e^{\lambda_1 t} \langle gh, X_t \rangle - e^{\lambda_1 (n+1)\sigma} \mathbb{P}_{X_t} \left(\langle gh, X_{(n+1)\sigma-t} \rangle \right) \\ &= e^{\lambda_1 t} \langle gh, X_t \rangle - e^{\lambda_1 (n+1)\sigma} \langle P_{(n+1)\sigma-t}^\beta (gh), X_t \rangle \\ &= e^{\lambda_1 t} \langle gh, X_t \rangle - e^{\lambda_1 t} \langle h P_{(n+1)\sigma-t}^h(g), X_t \rangle. \end{aligned} \quad (7.10)$$

Note that for any $s > 0$ and $x \in E$,

$$\begin{aligned} |g(x) - P_s^h g(x)| &= \left| \int_0^\infty \kappa e^{-\kappa t} P_t^h \phi(x) dt - \int_0^\infty \kappa e^{-\kappa t} P_{t+s}^h \phi(x) dt \right| \\ &= \left| \int_0^\infty \kappa e^{-\kappa t} P_t^h \phi(x) dt - \int_s^\infty \kappa e^{-\kappa t} P_t^h \phi(x) dt \right| \\ &\leq 2(1 - e^{-\kappa s}) \|\phi\|_\infty. \end{aligned}$$

It follows by this and (7.10) that

$$\sup_{t \in [n\sigma, (n+1)\sigma]} |\theta_{1,g}(n, \sigma, t)| \leq 2(1 - e^{-\kappa\sigma}) \|\phi\|_\infty \sup_{t \in [n\sigma, (n+1)\sigma]} W_t^h(X). \quad (7.11)$$

Since $W_t^h(X)$ converges to a finite limit almost surely, we obtain (1) from (7.11) by letting $n \rightarrow \infty$ and $\sigma \rightarrow 0$. For the proof of (3), note that by the Markov property of X ,

$$\begin{aligned}\theta_{3,g}(n, \sigma) &= e^{\lambda_1(n+1)\sigma} \mathbb{P}_{X_{n\sigma}}(\langle g_B h, X_\sigma \rangle) - \langle g_B h, h \rangle W_\infty^h(X) \\ &= e^{\lambda_1(n+1)\sigma} \langle P_\sigma^\beta(g_B h), X_{n\sigma} \rangle - \langle g_B h, h \rangle W_\infty^h(X) \\ &= e^{\lambda_1 n \sigma} \langle h P_\sigma^h(g_B), X_{n\sigma} \rangle - \langle g_B h, h \rangle W_\infty^h(X).\end{aligned}\tag{7.12}$$

Since $P_\sigma^h g_B \in \mathcal{B}_b^+(E)$, it follows from Lemma 7.5 that

$$\lim_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \langle h P_\sigma^h(g_B), X_{n\sigma} \rangle = \langle h P_\sigma^h(g_B), h \rangle W_\infty^h(X) = \langle g_B h, h \rangle W_\infty^h(X) \quad \mathbb{P}_\mu\text{-a.s.}$$

By this and (7.12) we obtain (3). It remains to prove (2). $\theta_{2,g_B}(n, \sigma, t)$ can be written as

$$\theta_{2,g_B}(n, \sigma, t) = \theta_{2,g_B}^{(1)}(n, \sigma, t) + \theta_{2,g_B}^{(2)}(n, \sigma, t) + \theta_{2,g_B}^{(3)}(n, \sigma, t)$$

where

$$\begin{aligned}\theta_{2,g_B}^{(1)}(n, \sigma, t) &:= e^{\lambda_1(n+1)\sigma} \mathbb{P}_\mu \left(\langle g_B h, X_{(n+1)\sigma}^* + I_\sigma^{*,n\sigma} \rangle | \mathcal{F}_t \right) \\ &\quad - e^{\lambda_1(n+1)\sigma} \mathbb{P}_\mu \left(\langle g_B h, X_{(n+1)\sigma}^* + I_\sigma^{*,n\sigma} \rangle | \mathcal{F}_{n\sigma} \right), \\ \theta_{2,g_B}^{(2)}(n, \sigma, t) &:= e^{\lambda_1(n+1)\sigma} \mathbb{P}_\mu \left(\sum_{i=1}^{N_{n\sigma}} \langle g_B h, I_\sigma^{i,n\sigma} \rangle 1_{\{\langle g_B h, I_\sigma^{i,n\sigma} \rangle < e^{-\lambda_1 n \sigma}\}} | \mathcal{F}_t \right) \\ &\quad - e^{\lambda_1(n+1)\sigma} \mathbb{P}_\mu \left(\sum_{i=1}^{N_{n\sigma}} \langle g_B h, I_\sigma^{i,n\sigma} \rangle 1_{\{\langle g_B h, I_\sigma^{i,n\sigma} \rangle < e^{-\lambda_1 n \sigma}\}} | \mathcal{F}_{n\sigma} \right), \\ \theta_{2,g_B}^{(3)}(n, \sigma, t) &:= e^{\lambda_1(n+1)\sigma} \mathbb{P}_\mu \left(\sum_{i=1}^{N_{n\sigma}} \langle g_B h, I_\sigma^{i,n\sigma} \rangle 1_{\{\langle g_B h, I_\sigma^{i,n\sigma} \rangle \geq e^{-\lambda_1 n \sigma}\}} | \mathcal{F}_t \right) \\ &\quad - e^{\lambda_1(n+1)\sigma} \mathbb{P}_\mu \left(\sum_{i=1}^{N_{n\sigma}} \langle g_B h, I_\sigma^{i,n\sigma} \rangle 1_{\{\langle g_B h, I_\sigma^{i,n\sigma} \rangle \geq e^{-\lambda_1 n \sigma}\}} | \mathcal{F}_{n\sigma} \right).\end{aligned}$$

Clearly for $i = 1, 2, 3$, $\{\theta_{2,g_B}^{(i)}(n, \sigma, t) : t \in [n\sigma, (n+1)\sigma]\}$ are \mathbb{P}_μ -martingales. Let

$$S_{\sigma, n\sigma}^{g_B} := e^{\lambda_1(n+1)\sigma} \sum_{i=1}^{N_{n\sigma}} \langle g_B h, I_\sigma^{i,n\sigma} \rangle$$

and

$$\widehat{S}_{\sigma, n\sigma}^{g_B} := e^{\lambda_1(n+1)\sigma} \sum_{i=1}^{N_{n\sigma}} \langle g_B h, I_\sigma^{i,n\sigma} \rangle 1_{\{\langle g_B h, I_\sigma^{i,n\sigma} \rangle < e^{-\lambda_1 n \sigma}\}}.$$

Then $\theta_{2,g_B}^{(2)}(n, \sigma, t) = \mathbb{P}_\mu \left(\widehat{S}_{\sigma, n\sigma}^{g_B} | \mathcal{F}_t \right) - \mathbb{P}_\mu \left(\widehat{S}_{\sigma, n\sigma}^{g_B} | \mathcal{F}_{n\sigma} \right)$, and

$$\theta_{2,g_B}^{(3)}(n, \sigma, t) = \mathbb{P}_\mu \left(S_{\sigma, n\sigma}^{g_B} - \widehat{S}_{\sigma, n\sigma}^{g_B} | \mathcal{F}_t \right) - \mathbb{P}_\mu \left(S_{\sigma, n\sigma}^{g_B} - \widehat{S}_{\sigma, n\sigma}^{g_B} | \mathcal{F}_{n\sigma} \right).$$

Suppose $\varepsilon > 0$. By Doob's maximal inequality and Jensen's inequality, we have

$$\begin{aligned}&\mathbb{P}_\mu \left(\sup_{t \in [n\sigma, (n+1)\sigma]} |\theta_{2,g_B}^{(2)}(n, \sigma, t)| > \varepsilon \right) \\ &\leq \frac{1}{\varepsilon^2} \mathbb{P}_\mu \left(|\theta_{2,g_B}^{(2)}(n, \sigma, (n+1)\sigma)|^2 \right)\end{aligned}$$

$$\begin{aligned}
&= \frac{1}{\varepsilon^2} \mathbb{P}_\mu \left[\left| \mathbb{P}_\mu \left(\widehat{S}_{\sigma, n\sigma}^{g_B} - \mathbb{P}_\mu \left(\widehat{S}_{\sigma, n\sigma}^{g_B} | \mathcal{F}_{n\sigma} \right) | \mathcal{F}_{(n+1)\sigma} \right) \right|^2 \right] \\
&\leq \frac{1}{\varepsilon^2} \mathbb{P}_\mu \left(\left| \widehat{S}_{\sigma, n\sigma}^{g_B} - \mathbb{P}_\mu \left(\widehat{S}_{\sigma, n\sigma}^{g_B} | \mathcal{F}_{n\sigma} \right) \right|^2 \right).
\end{aligned}$$

We have proved in the proof of Lemma 7.3 that $\sum_{n=1}^{\infty} \mathbb{P}_\mu \left(\left| \widehat{S}_{\sigma, n\sigma}^{g_B} - \mathbb{P}_\mu \left(\widehat{S}_{\sigma, n\sigma}^{g_B} | \mathcal{F}_{n\sigma} \right) \right|^2 \right) < \infty$. Thus

$$\sum_{n=1}^{\infty} \mathbb{P}_\mu \left(\sup_{t \in [n\sigma, (n+1)\sigma]} |\theta_{2, g_B}^{(2)}(n, \sigma, t)| > \varepsilon \right) < \infty$$

and consequently by Borel-Cantelli lemma

$$\lim_{n \rightarrow \infty} \sup_{t \in [n\sigma, (n+1)\sigma]} |\theta_{2, g_B}^{(2)}(n, \sigma, t)| = 0 \quad \mathbb{P}_\mu\text{-a.s.} \quad (7.13)$$

Similarly by Doob's maximal inequality and Jensen's inequality,

$$\begin{aligned}
&\mathbb{P}_\mu \left(\sup_{t \in [n\sigma, (n+1)\sigma]} |\theta_{2, g_B}^{(3)}(n, \sigma, t)| > \varepsilon \right) \\
&\leq \frac{1}{\varepsilon} \mathbb{P}_\mu \left(|\theta_{2, g_B}^{(3)}(n, \sigma, (n+1)\sigma)| \right) \\
&= \frac{1}{\varepsilon} \mathbb{P}_\mu \left[\left| \mathbb{P}_\mu \left(S_{\sigma, n\sigma}^{g_B} - \widehat{S}_{\sigma, n\sigma}^{g_B} - \mathbb{P}_\mu \left(S_{\sigma, n\sigma}^{g_B} - \widehat{S}_{\sigma, n\sigma}^{g_B} | \mathcal{F}_{n\sigma} \right) | \mathcal{F}_{(n+1)\sigma} \right) \right| \right] \\
&\leq \frac{1}{\varepsilon} \left[\mathbb{P}_\mu \left(S_{\sigma, n\sigma}^{g_B} - \widehat{S}_{\sigma, n\sigma}^{g_B} \right) + \mathbb{P}_\mu \left(\mathbb{P}_\mu \left(S_{\sigma, n\sigma}^{g_B} - \widehat{S}_{\sigma, n\sigma}^{g_B} | \mathcal{F}_{n\sigma} \right) \right) \right] \\
&= \frac{2}{\varepsilon} \mathbb{P}_\mu \left(S_{\sigma, n\sigma}^{g_B} - \widehat{S}_{\sigma, n\sigma}^{g_B} \right).
\end{aligned}$$

We have showed in the proof of Lemma 7.3 that $\sum_{n=1}^{\infty} \mathbb{P}_\mu \left(S_{\sigma, n\sigma}^{g_B} - \widehat{S}_{\sigma, n\sigma}^{g_B} \right) < \infty$. Thus by Borel-Cantelli lemma

$$\lim_{n \rightarrow \infty} \sup_{t \in [n\sigma, (n+1)\sigma]} |\theta_{2, g_B}^{(3)}(n, \sigma, t)| = 0 \quad \mathbb{P}_\mu\text{-a.s.} \quad (7.14)$$

Using Doob's maximal inequality and Jensen's inequality again, we get

$$\mathbb{P}_\mu \left(\sup_{t \in [n\sigma, (n+1)\sigma]} |\theta_{2, g_B}^{(1)}(n, \sigma, t)| > \varepsilon \right) \leq \frac{1}{\varepsilon^2} e^{2\lambda_1(n+1)\sigma} \mathbb{P}_\mu \left[\text{Var} \left(\langle g_B h, X_{(n+1)\sigma}^* + I_{\sigma}^{*, n\sigma} \rangle | \mathcal{F}_{n\sigma} \right) \right]. \quad (7.15)$$

Recall that given \mathcal{F}_t , $(X_{s+t}^* + I_s^{*, t})_{s \geq 0}$ is equal in distribution to $((X_s^*)_{s \geq 0}; \mathbb{P}_{X_t})$. It is known that for $\nu \in \mathcal{M}_F(E)$ and $f \in \mathcal{B}_b^+(E)$, the second moment of $\langle f, X_t^* \rangle$ can be expressed as

$$\text{Var}_\nu \left(\langle f, X_t^* \rangle \right) = \int_0^t \langle P_s^{\beta^*} \left[(2\alpha + b^*)(P_{t-s}^{\beta^*} f)^2 \right], \nu \rangle ds,$$

where $b^*(x) := \int_{(0, \infty)} r^2 \pi^*(x, dr) = \int_{(0, \infty)} r^2 e^{-w(x)r} \pi(x, dr)$. Thus we can continue the calculation in (7.15) to get

$$\begin{aligned}
&\mathbb{P}_\mu \left(\sup_{t \in [n\sigma, (n+1)\sigma]} |\theta_{2, g_B}^{(1)}(n, \sigma, t)| > \varepsilon \right) \\
&\leq \frac{1}{\varepsilon^2} e^{2\lambda_1(n+1)\sigma} \mathbb{P}_\mu \left[\text{Var}_{X_{n\sigma}} \left(\langle g_B h, X_\sigma^* \rangle \right) \right] \\
&= \frac{1}{\varepsilon^2} e^{2\lambda_1(n+1)\sigma} \mathbb{P}_\mu \left[\int_0^\sigma \langle P_s^{\beta^*} \left[(2\alpha + b^*)(P_{\sigma-s}^{\beta^*} (g_B h))^2 \right], X_{n\sigma} \rangle ds \right]
\end{aligned}$$

$$\begin{aligned}
&= \frac{1}{\varepsilon^2} e^{2\lambda_1(n+1)\sigma} \int_0^\sigma \langle P_{n\sigma}^\beta P_s^{\beta*} [(2\alpha + b^*)(P_{\sigma-s}^{\beta*}(g_B h))^2], \mu \rangle ds \\
&\leq \frac{1}{\varepsilon^2} e^{2\lambda_1(n+1)\sigma} \int_0^\sigma \langle P_{n\sigma+s}^\beta [(2\alpha + b^*)(P_{\sigma-s}^{\beta*}(g_B h))^2], \mu \rangle ds \\
&= \frac{1}{\varepsilon^2} e^{\lambda_1 n \sigma + 2\lambda_1 \sigma} \int_0^\sigma e^{-\lambda_1 s} \langle P_{n\sigma+s}^h \left[\frac{2\alpha + b^*}{h} (P_{\sigma-s}^{\beta*}(g_B h))^2 \right], h\mu \rangle ds. \tag{7.16}
\end{aligned}$$

Since g_B is compactly supported, for $s \in [0, \sigma)$, $\|P_{\sigma-s}^{\beta*}(g_B h)\|_\infty \leq \|P_{\sigma-s}^\beta(g_B h)\|_\infty \leq e^{\|\beta\|\infty\sigma} \|g_B h\|_\infty$. In addition, for each $x \in E$, $P_{\sigma-s}^{\beta*}(g_B h)(x) = e^{-\lambda_1(\sigma-s)} h(x) \theta_{g_B h}^*(\sigma-s, x) \leq e^{-\lambda_1\sigma} \|\theta_{g_B h}^*\|_\infty h(x)$. Thus we get for $s \in [0, \sigma)$,

$$\left(P_{\sigma-s}^{\beta*}(g_B h)(x) \right)^2 \leq c_1 \wedge c_2 h(x) \wedge c_3 h(x)^2 \quad \text{for all } x \in E. \tag{7.17}$$

Here c_1, c_2, c_3 are positive constants. We have by (7.17)

$$\begin{aligned}
\int_0^\sigma e^{-\lambda_1 s} \langle P_{n\sigma+s}^h \left[\frac{2\alpha}{h} (P_{\sigma-s}^{\beta*}(g_B h))^2 \right], h\mu \rangle ds &\leq \int_0^\sigma e^{-\lambda_1 s} \langle P_{n\sigma+s}^h (2c_2\alpha), h\mu \rangle ds \\
&\leq 2c_2 \|\alpha\|_\infty \langle h, \mu \rangle \int_0^\sigma e^{-\lambda_1 s} ds. \tag{7.18}
\end{aligned}$$

On the other hand,

$$\int_0^\sigma e^{-\lambda_1 s} \langle P_{n\sigma+s}^h \left[\frac{b^*}{h} (P_{\sigma-s}^{\beta*}(g_B h))^2 \right], h\mu \rangle ds \leq \int_0^\sigma e^{-\lambda_1 s} \langle P_{n\sigma+s}^h \left(c_1 \frac{b^*}{h} \wedge c_2 b^* \wedge c_3 b^* h \right), h\mu \rangle ds.$$

Let $l(x) := c_1 \frac{b^*}{h}(x) \wedge c_2 b^*(x) \wedge c_3 b^*(x) h(x)$ for $x \in E$. Assumption 4(ii) implies that $l(x) \in L^2(E, \tilde{m})$. Thus by (3.6) for $n\sigma > 1$ and $x \in E$,

$$P_{n\sigma+s}^h(l)(x) \leq \langle l, h^2 \rangle + e^{-\lambda_h(n\sigma+s-1)} \tilde{a}_2(x)^{1/2} \|l\|_{L^2(E, \tilde{m})}.$$

Consequently for $n\sigma > 1$,

$$\begin{aligned}
&\int_0^\sigma e^{-\lambda_1 s} \langle P_{n\sigma+s}^h \left[\frac{b^*}{h} (P_{\sigma-s}^{\beta*}(g_B h))^2 \right], h\mu \rangle ds \\
&\leq \int_0^\sigma e^{-\lambda_1 s} \langle P_{n\sigma+s}^h(l), h\mu \rangle ds \\
&\leq \langle l, h^2 \rangle \langle h, \mu \rangle \int_0^\sigma e^{-\lambda_1 s} ds + e^{-\lambda_h(n\sigma-1)} \|l\|_{L^2(E, \tilde{m})} \langle \tilde{a}_2^{1/2} h, \mu \rangle \int_0^\sigma e^{-(\lambda_1 + \lambda_h)s} ds. \tag{7.19}
\end{aligned}$$

Since $\lambda_1 < 0$, it follows from (7.18) and (7.19) that

$$\sum_{n=1}^\infty e^{\lambda_1 n \sigma} \int_0^\sigma e^{-\lambda_1 s} \langle P_{n\sigma+s}^h \left[\frac{2\alpha + b^*}{h} (P_{\sigma-s}^{\beta*}(g_B h))^2 \right], h\mu \rangle ds < \infty.$$

Thus by (7.16), we get $\sum_{n=1}^\infty \mathbb{P}_\mu \left(\sup_{t \in [n\sigma, (n+1)\sigma]} |\theta_{2, g_B}^{(1)}(n, \sigma, t)| > \varepsilon \right) < \infty$. By Borel-Cantelli Lemma

$$\lim_{n \rightarrow \infty} \sup_{t \in [n\sigma, (n+1)\sigma]} |\theta_{2, g_B}^{(1)}(n, \sigma, t)| = 0 \quad \mathbb{P}_\mu\text{-a.s.} \tag{7.20}$$

We obtain (2) by (7.13), (7.14) and (7.20). This completes the proof. \square

Lemma 7.7. *Suppose Assumptions 1-6 hold. Then for any $\mu \in \mathcal{M}_c(E)$ and $\phi \in C_0^+(E)$,*

$$\lim_{t \rightarrow \infty} e^{\lambda_1 t} \langle \phi h, X_t \rangle = \langle \phi h, h \rangle W_\infty^h(X) \quad \mathbb{P}_\mu\text{-a.s.} \tag{7.21}$$

Proof. For any $\kappa > 0$, we have

$$\begin{aligned} |e^{\lambda_1 t} \langle \phi h, X_t \rangle - \langle \phi h, h \rangle W_\infty^h(X)| &\leq e^{\lambda_1 t} |\langle \kappa U^\kappa \phi - \phi | h, X_t \rangle| + |e^{\lambda_1 t} \langle (\kappa U^\kappa \phi) h, X_t \rangle - \langle \phi h, h \rangle W_\infty^h(X)| \\ &\leq \|\kappa U^\kappa \phi - \phi\|_\infty W_t^h(X) + |e^{\lambda_1 t} \langle (\kappa U^\kappa \phi) h, X_t \rangle - \langle \phi h, h \rangle W_\infty^h(X)|. \end{aligned}$$

In view of (7.7) and Lemma 7.6, we conclude (7.21) by letting $t \rightarrow \infty$ and $\kappa \rightarrow \infty$. \square

Proof of Theorem 2.13. This theorem follows immediately from Lemma 7.1, Lemma 7.2 and Lemma 7.7. \square

8 Examples

In this section, we give examples of superprocesses where Assumptions 1-6 are satisfied and Theorem 2.11-Theorem 2.13 hold. Since the paper is already long, we leave the detailed verifications of assumptions for these examples in the Appendix of this paper. We notice that Example 8.1 and 8.2 are also studied in [16]. In Example 8.5 we consider a class of super α -stable-like processes which includes super α -stable processes as a special case.

Example 8.1. Suppose $E = \mathbb{R}^d$ ($d \geq 1$) and $\xi = (\xi_t; \Pi_x, x \in \mathbb{R}^d)$ is an inward Ornstein-Uhlenbeck (OU) process on \mathbb{R}^d with infinitesimal generator

$$\mathcal{L} := \frac{1}{2} \sigma^2 \Delta - cx \cdot \nabla \quad \text{on } \mathbb{R}^d$$

where $\sigma, c > 0$. Without loss of generality, we assume that $\sigma = 1$. Let dx denote the Lebesgue measure on \mathbb{R}^d and $m(dx) := \left(\frac{c}{\pi}\right)^{d/2} e^{-c|x|^2} dx$. Then ξ is symmetric with respect to the probability measure m . Let $\psi(\lambda)$ be a spatially independent branching mechanism given by (2.20) with $\beta > 0$, $\psi(\infty) = \infty$ and $\int_{(1,\infty)} y^p \pi(dy) < \infty$ for some $p \in (1, 2]$. For this (ξ, ψ) -superdiffusion Assumptions 1-6 are satisfied with $\lambda_1 = -\beta$, $h(x) \equiv 1$ and $w(x) \equiv z_\psi$ where $z_\psi := \sup\{\lambda \geq 0 : \psi(\lambda) \leq 0\} \in (0, \infty)$.

Example 8.2. Suppose $E = \mathbb{R}^d$ ($d \geq 1$) and $\xi := (\xi_t; \Pi_x, x \in \mathbb{R}^d)$ is an outward OU process on \mathbb{R}^d with infinitesimal generator

$$\mathcal{L} := \frac{1}{2} \sigma^2 \Delta + cx \cdot \nabla \quad \text{on } \mathbb{R}^d$$

where $\sigma, c > 0$. Without loss of generality, we assume $\sigma = 1$. Let $m(dx) := \left(\frac{c}{\pi}\right)^{-d/2} e^{c|x|^2} dx$. Then ξ is symmetric with respect to m . Let $\psi(\lambda)$ be a spatially independent branching mechanism given by (2.20) with $\beta > cd$, $\psi(\infty) = \infty$ and $\int_{(1,\infty)} y^p \pi(dy) < \infty$ for some $p \in (1, 2]$. Then Assumptions 1-6 are satisfied with $\lambda_1 = cd - \beta$, $h(x) = \left(\frac{c}{\pi}\right)^{d/2} e^{-c|x|^2}$ and $w(x) \equiv z_\psi$ where $z_\psi := \sup\{\lambda \geq 0 : \psi(\lambda) \leq 0\} \in (0, \infty)$.

Example 8.3. Let $(Y = (Y_t)_{t \geq 0}, \Pi_x)$ be a diffusion on \mathbb{R}^d ($d \geq 3$) with generator

$$\mathcal{A} := \rho(x)^{-1} \sum_{i,j=1}^d \frac{\partial}{\partial x_i} \left(\rho(x) a_{ij}(x) \frac{\partial}{\partial x_j} \right) \quad \text{on } \mathbb{R}^d,$$

where the diffusion matrix $A(x) = (a_{ij}(x))_{i,j}$ is uniformly elliptic and symmetric with $a_{ij} \in C_b^1(\mathbb{R}^d)$ and function $\rho \in C_b^1(\mathbb{R}^d)$ is bounded between two positive constants. Here $C_b^1(\mathbb{R}^d)$ denotes the space of bounded continuous functions on \mathbb{R}^d whose first order derivatives are bounded and continuous. Clearly this includes Brownian motion as a special case. Note that we can rewrite \mathcal{A} as

$$\mathcal{A} = \sum_{i,j=1}^d \frac{\partial}{\partial x_i} \left(a_{ij}(x) \frac{\partial}{\partial x_j} \right) + \sum_{j=1}^d \left(\sum_{i=1}^d a_{ij}(x) \frac{\partial \log \rho}{\partial x_i} \right) \frac{\partial}{\partial x_j} \quad \text{on } \mathbb{R}^d.$$

Define $m(dx) := \rho(x)dx$. Then Y is symmetric with respect to m . Suppose E is a bounded $C^{1,1}$ domain in \mathbb{R}^d and $\xi := Y^E$ is the subprocess of Y killing upon leaving E . Let $\psi_\beta(x, \lambda) := -\beta(x)\lambda + \alpha(x)\lambda^2 + \int_{(0, \infty)} (e^{-\lambda y} - 1 + \lambda y) \pi(x, dy)$ where $\beta \in C_b^1(\mathbb{R}^d)$, $0 < \alpha \in C_b^1(\mathbb{R}^d) \cap \mathcal{B}^+(\mathbb{R}^d)$, $\pi(x, dy)$ satisfies

$$\sup_{x \in \mathbb{R}^d} \int_{(0, \infty)} y \log^* y \pi(x, dy) < \infty, \quad (8.1)$$

and all the first partial derivatives of $\psi_\beta(x, \lambda)$ are continuous. We will show in Appendix A.2 that Assumptions 1-6 are satisfied for such (ξ, ψ_β) -superdiffusions.

Example 8.4. Suppose E is a locally compact separable metric space and m is a σ -finite nonnegative Radon measure on E with full support. Suppose ξ is an m -symmetric Hunt process on E with transition density function $p(t, x, y)$ which is positive, continuous and symmetric in (x, y) . Define $a_t(x) := p(t, x, x)$ for $x \in E$ and $t > 0$. We assume that

- (1) for each $t > 0$, $a_t(x) \in L^1(E, m)$;
- (2) there exists $t_0 > 0$ such that $a_{t_0}(x) \in L^2(E, m)$.

Define $\hat{a}_t(x) := p^\beta(t, x, x)$ for $x \in E$ and $t > 0$. Under conditions (1) and (2), \hat{a}_t satisfies

- (i) for any $t > 0$, $\hat{a}_t(x) \in L^1(E, m)$;
- (ii) there exists $t_0 > 0$ such that $\hat{a}_t(x) \in L^2(E, m)$ for all $t \geq t_0$.

Property (i) implies that for $t > 0$, the Feynman-Kac semigroup P_t^β is a Hilbert-Schmidt operator in $L^2(E, m)$, and hence compact. Let $\mathcal{L}^{(\beta)}$ be the infinitesimal operator of P_t^β , and $\sigma(\mathcal{L}^{(\beta)})$ be the spectrum of the self-adjoint operator $\mathcal{L}^{(\beta)}$. We know by [29] that $\sigma(\mathcal{L}^{(\beta)})$ consists of at most countable eigenvalues. By Jentzsch's theorem, $\lambda_1 := \inf\{-\lambda : \lambda \in \sigma(\mathcal{L}^{(\beta)})\}$ is an eigenvalue of multiplicity 1, and the corresponding eigenfunction h can be chosen to be continuous and positive on E with $\int_E h(x)^2 m(dx) = 1$. We assume $\lambda_1 < 0$. The h -transformed semigroup P_t^h admits an integral kernel $p^h(t, x, y)$ with respect to the measure $\tilde{m}(dx) := h(x)^2 m(dx)$, which is related to $p^\beta(t, x, y)$ by (3.5). Define $\tilde{a}_t(x) := p^h(t, x, x) = e^{\lambda_1 t} \frac{\hat{a}_t(x)}{h(x)^2}$ for $x \in E$. We assume in addition that

- (3) for all $f \in C_0(E)$, $\|P_t^h f - f\|_\infty \rightarrow 0$ as $t \rightarrow 0$.

Let X be a (P_t, ψ_β) -superprocess with spatial motion ξ satisfying conditions (1)-(3) and the branching mechanism $\psi_\beta(x, \lambda)$ given by (2.1) with $\beta(x) \in \mathcal{B}_b(E)$, $\alpha \in \mathcal{B}_b^+(E)$ and $\pi(x, dy)$ satisfying

$$\sup_{x \in E} \int_{(0, \infty)} y^2 \pi(x, dy) < \infty, \quad (8.2)$$

We assume in addition that ψ_β satisfies condition (2.21) in Subsection 2.3. Then our Assumptions 1-6 are satisfied by this class of superprocesses with λ_1, h defined as above and $w(x) := -\log P_{\delta_x} (\exists t \geq 0 : \langle 1, X_t \rangle = 0)$. This example covers Example 4.1-4.5 in [8].

Example 8.5. Suppose $E = \mathbb{R}^d$ ($d \geq 1$) and $m(dx) = dx$ is the Lebesgue measure on \mathbb{R}^d . Suppose $(\xi; \Pi_x, x \in \mathbb{R}^d)$ is an α -stable-like process on \mathbb{R}^d with $\alpha \in (0, 2)$. An α -stable-like process on \mathbb{R}^d is a symmetric Feller process on \mathbb{R}^d whose Dirichlet form $(\mathcal{E}, \mathcal{F})$ on $L^2(\mathbb{R}^d; dx)$ is given by

$$\mathcal{F} = \left\{ u \in L^2(\mathbb{R}^d; dx) : \int \int_{\mathbb{R}^d \times \mathbb{R}^d} \frac{(u(x) - u(y))^2}{|x - y|^{d+\alpha}} dx dy < \infty \right\},$$

$$\mathcal{E}(u, u) = \int \int_{\mathbb{R}^d \times \mathbb{R}^d} (u(x) - u(y))^2 \frac{c(x, y)}{|x - y|^{d+\alpha}} dx dy,$$

where $c(x, y)$ is a symmetric function on $\mathbb{R}^d \times \mathbb{R}^d$ that is bounded between two positive constants. Clearly this includes symmetric α -stable process on \mathbb{R}^d as a special case. Let $\psi_\beta(x, \lambda)$ be a branching mechanism given by (2.1) where $\beta \in \mathcal{B}_b(\mathbb{R}^d)$ has a compact support, $\alpha \in \mathcal{B}_b^+(\mathbb{R}^d)$ and π satisfies (8.2). Let X be a (ξ, ψ_β) -superprocess. Here we assume in addition that ψ_β satisfies condition (2.21) of Section 2.3. It is proved in [6, Theorem 4.14] that the transition density function $p(t, x, y)$ of a α -stable-like process is bounded and continuous in (x, y) for each $t > 0$ and

$$p(t, x, y) \asymp t^{-d/\alpha} \wedge \frac{t}{|x - y|^{d+\alpha}} \quad \text{for all } x, y \in \mathbb{R}^d \text{ and } t > 0. \quad (8.3)$$

It follows that for each $t > 0$, the transition semigroup P_t of ξ maps bounded functions to continuous functions, and P_t is bounded from $L^p(\mathbb{R}^d, dx)$ to $L^q(\mathbb{R}^d, dx)$ for $1 \leq p \leq q \leq \infty$. Furthermore, for each $t > 0$, P_t^β maps bounded functions to continuous functions, and P_t^β is bounded from $L^p(\mathbb{R}^d, dx)$ to $L^q(\mathbb{R}^d, dx)$ for $1 \leq p \leq q \leq \infty$. Define $\mathcal{E}_1(u, u) := \mathcal{E}(u, u) + \int_{\mathbb{R}^d} u(x)^2 dx$ for $u \in \mathcal{F}$, and $\lambda_0 := \inf\{\mathcal{E}(u, u) : u \in \mathcal{F} \text{ with } \int_{\mathbb{R}^d} u(x)^2 dx = 1\} \geq 0$. The semigroup P_t^β associates with a quadratic form $(\mathcal{E}^{(\beta)}, \mathcal{F})$ where

$$\mathcal{E}^{(\beta)}(u, u) = \mathcal{E}(u, u) - \int_{\mathbb{R}^d} u(x)^2 \beta(x) dx \quad \text{for } u \in \mathcal{F}.$$

Define $\lambda_1 := \inf\{\mathcal{E}^{(\beta)}(u, u) : u \in \mathcal{F} \text{ with } \int_{\mathbb{R}^d} u(x)^2 dx = 1\} \geq -\|\beta^+\|_\infty$. We use $\sigma(\mathcal{E}^{(\beta)})$ to denote the spectrum of $-\mathcal{L}^{(\beta)}$, where $\mathcal{L}^{(\beta)}$ is the self-adjoint operator associated with $(\mathcal{E}^{(\beta)}, \mathcal{F})$. Clearly the Dirichlet form $(\mathcal{E}, \mathcal{F})$ is comparable to that of the symmetric α -stable process. Thus by applying the same argument as in [32], we can show that the embedding of $(\mathcal{F}, \mathcal{E}_1)$ into $L^2(\mathbb{R}^d, \beta(x) dx)$ is compact. Then by Friedrichs theorem, the spectrum of $\sigma(\mathcal{E}^{(\beta)})$ less than λ_0 consists of only isolated eigenvalues with finite multiplicities. We assume $\lambda_1 < 0$, and hence $\lambda_1 < \lambda_0$ is automatically true. Let h be the normalized nonnegative L^2 -eigenfunction corresponding to λ_1 . It holds that $h = e^{\lambda_1 t} P_t^\beta h$ on E . Since P_t^β maps $L^2(\mathbb{R}^d, dx)$ into $L^\infty(\mathbb{R}^d, dx)$ and maps $\mathcal{B}_b(\mathbb{R}^d)$ into $C(\mathbb{R}^d)$, h is a bounded continuous function on \mathbb{R}^d . Moreover h is positive everywhere by the irreducibility of ξ and the positivity of $\exp\left(\int_0^t \beta(\xi_s) ds\right)$. For such (ξ, ψ_β) -superprocess, Assumptions 1-6 are satisfied with λ_1 , h defined as above and $w(x) := -\log P_{\delta_x} (\exists t \geq 0, \langle 1, X_t \rangle = 0)$.

A Appendix

A.1 Kuznetsov measure for superdiffusions

Suppose the operator \mathcal{L} is defined by the formula:

$$\mathcal{L} := \sum_{i,j=1}^d \frac{\partial}{\partial x_j} a_{ij}(x) \frac{\partial}{\partial x_j} + \sum_{i=1}^d b_i(x) \frac{\partial}{\partial x_i} \quad \text{on } \mathbb{R}^d,$$

where the matrix $A(x) := (a_{ij}(x))_{i,j}$ is symmetric and positive definite, and all a_{ij} and b_i are bounded and (globally) Hölder continuous on \mathbb{R}^d . It is known (cf. [14, Chapter 2]) that there exists a diffusion process on \mathbb{R}^d , called the \mathcal{L} -diffusion, whose transition density function is a fundamental solution of the equation $\partial u / \partial t = \mathcal{L}u$. In this subsection, we assume $E \subset \mathbb{R}^d$ is a nonempty domain and ξ is the subprocess of the \mathcal{L} -diffusion on E . We assume that the branching mechanism $\psi_\beta(x, \lambda)$ is given by (2.1) and all the first partial derivatives of $\psi_\beta(x, \lambda)$ are continuous. This (ξ, ψ_β) -superprocess is also called (ξ, ψ_β) -superdiffusion. Let X be a (ξ, ψ_β) -superdiffusion. We are concerned with the set $E_0 = \{x \in E : \text{Kuznetsov measure } \mathbb{N}_x \text{ exists}\}$. By the argument in Subsection 2.3, we know that (2.13) is a sufficient condition for the existence of \mathbb{N}_x . We recall that for every open set $D \subset E$ and $t \geq 0$, there is a random measure \tilde{X}_t^D concentrated on the boundary of $[0, t) \times D$ such that (2.7) and (2.8) hold for every $\mu \in \mathcal{M}_F(E)$ and every $f \in \mathcal{B}_b^+([0, t] \times E)$. We

also recall that X_t is the projection of \tilde{X}_t^E on E . For every $x \in E$, let \mathbb{O}_x be the set of open sets in E that contains x . Then condition (2.13) is satisfied if

$$\mathbf{P}_{\delta_x} \left(\tilde{X}_t^D = 0 \right) > 0 \quad \text{for all } t > 0 \text{ and } D \in \mathbb{O}_x. \quad (\text{A.1})$$

It follows from the Markov property of branching exit Markov systems that for any $D_1, D_2 \in \mathbb{O}_x$ with $D_1 \subset D_2$, and any $0 < s \leq t < \infty$,

$$\{\tilde{X}_s^{D_1} = 0\} \subset \{\tilde{X}_t^{D_2} = 0\} \quad \mathbf{P}_{\delta_x}\text{-a.s.}$$

Thus condition (A.1) is equivalent to that: There is $\delta > 0$ sufficiently small such that

$$\mathbf{P}_{\delta_x} \left(\tilde{X}_t^{B_r} = 0 \right) > 0 \quad \text{for all } t > 0 \text{ and } 0 < r \leq \delta.$$

Here $B_r := B(x, r)$ denotes the ball centered at x with radius r .

In the remainder of this subsection, we assume ψ is a spatially independent branching mechanism given by (2.20). Suppose $((Y_t)_{t \geq 0}; \mathbf{P}_y, y \in \mathbb{R}^+)$ is a one dimensional CB process with branching mechanism ψ and $\mathbf{P}_y(Y_0 = y) = 1$. The process Y is called *subcritical*, *critical* or *supercritical* according to $\psi'(0+) >$, $=$ or < 0 . It is well-known that $\mathbf{P}_y(\lim_{t \rightarrow \infty} Y_t = 0) = e^{-y z_\psi}$, where $z_\psi := \sup\{\lambda \geq 0, \psi(\lambda) \leq 0\} \in [0, \infty]$. Moreover, by the Markov property of Y , we have

$$\mathbf{P}_y \left(e^{-z_\psi Y_t} \right) = e^{-y z_\psi} \quad \text{for all } y \geq 0 \text{ and } t \geq 0.$$

In the subcritical and critical cases, $z_\psi = 0$, while in the supercritical case, $z_\psi \in (0, \infty)$ if $\psi(\infty) = \infty$, and otherwise $z_\psi = \infty$. Given $z_\psi \in (0, \infty)$, conditioned on the event $\{\lim_{t \rightarrow \infty} Y_t = 0\}$, Y is a CB process with branching mechanism

$$\psi^*(\lambda) = \psi(\lambda + z_\psi) = \psi'(z_\psi)\lambda + a\lambda^2 + \int_{(0, \infty)} (e^{-\lambda x} - 1 + \lambda x) e^{-x z_\psi} \eta(dx). \quad (\text{A.2})$$

Since $(\psi^*)'(0+) = \psi'(z_\psi) > 0$, the conditioned process is subcritical (cf. Lemma 2 in [2]).

Lemma A.1. *Suppose ψ given by (2.20) satisfies $z_\psi < \infty$ and that*

$$\int_N^\infty ds \left[\int_{z_\psi}^s \psi(u) du \right]^{-1/2} < \infty \quad \text{for some } N > z_\psi. \quad (\text{A.3})$$

Then for any bounded open set $Q = (t_1, t_2) \times B$, where $0 \leq t_1 < t_2 < \infty$ and $B := B(x_0, r)$ with $x_0 \in E$ and $r > 0$, there is a function $v^0(s, x) \in C^2(Q)$ such that

$$\left\{ \begin{array}{l} \frac{\partial v^0}{\partial s} + L v^0 \leq \psi(v^0), \quad (s, x) \in Q, \\ v^0(s, x) \geq z_\psi, \quad (s, x) \in Q, \\ \lim_{Q \ni (s, x) \rightarrow z} v^0(s, x) = \infty, \quad z \in \mathcal{T}_Q, \end{array} \right. \quad (\text{A.4})$$

where $\mathcal{T}_Q := ((t_1, t_2) \times \partial B) \cup (\{t_2\} \times \bar{B})$ is a total set of ∂Q .

Proof. The idea of this proof is similar to that of [14, Theorem 5.3.1]. We only need to prove the result for sufficiently small $t_2 - t_1 + r$. Note that (A.3) is equivalent to

$$\int_N^\infty ds \left[\int_0^s \psi^*(r) dr \right]^{-1/2} < \infty \quad \text{for some } N > 0,$$

where ψ^* is defined in (A.2). By [14, Lemma 5.3.1], for sufficiently small $t_2 - t_1$ there is a nonnegative solution $u^*(s)$ of the following problem:

$$\begin{cases} \frac{\partial u^*}{\partial s} \leq \psi^*(u^*), & s \in (t_1, t_2), \\ \lim_{(t_1, t_2) \ni s \rightarrow t_2} u^*(s) = \infty. \end{cases}$$

Take $u(s) := z_\psi + u^*(s)$ for $s \in (t_1, t_2)$. Using the fact that $\psi^*(\lambda) = \psi(\lambda + z_\psi)$, it is easy to check that u satisfies (A.5):

$$\begin{cases} \frac{\partial u}{\partial s} \leq \psi(u), & s \in (t_1, t_2), \\ u(s) \geq z_\psi, & s \in (t_1, t_2). \\ \lim_{(t_1, t_2) \ni s \rightarrow t_2} u(s) = \infty, \end{cases} \quad (\text{A.5})$$

On the other hand, by [14, Lemma 5.3.4] and the fact that $\psi^*(\lambda) = \psi(\lambda + z_\psi)$, for sufficiently small r , there is a nonnegative solution $v(x)$ of the following problem:

$$\begin{cases} Lv \leq \psi(v), & x \in B, \\ \lim_{B \ni x \rightarrow z} v(x) = \infty, & z \in \partial B. \end{cases}$$

Hence $v^0(s, x) := u(s) + v(x)$ is a solution of (A.4). \square

Lemma A.2. [Comparison Principle] Suppose ψ is given by (2.20) with $z_\psi < \infty$ and that Q is a bounded regular open set in $[0, \infty) \times \mathbb{R}^d$. Then $u \leq v$ in Q assuming that

- (a) $u, v \in C^2(Q)$;
- (b) $\frac{\partial u}{\partial s} + Lu - \psi(u) \geq \frac{\partial v}{\partial s} + Lv - \psi(v)$ in Q ;
- (c) u is bounded from above and $v \geq z_\psi$ in Q .
- (d) for every $\tilde{z} \in \mathcal{T}_Q$, $\limsup_{Q \ni z \rightarrow \tilde{z}} [u(z) - v(z)] \leq 0$.

Proof. The proof is similar to that of [14, Theorem 5.2.3] by using the fact that $\psi(\lambda)$ is an increasing function in $\lambda \in [z_\psi, \infty)$. We omit the details here. \square

Lemma A.3. If $x \in E$ satisfies the following condition: there exist an open set $D \in \mathcal{O}_x$ and a function ψ in the form of (2.20) with $z_\psi < \infty$ such that (A.3) holds and

$$\psi_\beta(x, \lambda) \geq \psi(\lambda) \quad \text{for all } x \in D \text{ and } \lambda \geq 0, \quad (\text{A.6})$$

then $\mathbb{P}_{\delta_x}(X_t = 0) > 0$ for all $t > 0$ and hence $x \in E_0$.

Proof. By the argument in the beginning of this subsection, it suffices to prove that for $\delta > 0$ small enough such that $B_\delta := B(x, \delta) \subset D$, we have

$$\mathbb{P}_{\delta_x}(\tilde{X}_t^{B_r} = 0) > 0 \quad \text{for all } t > 0 \text{ and } B_r := B(x, r) \text{ with } r \in (0, \delta]. \quad (\text{A.7})$$

Fix $r \in (0, \delta]$ and an arbitrary $T > 0$. For any $\lambda > 0$, let

$$\tilde{u}_\lambda^{B_r}(s, y) := -\log \mathbb{P}_{\delta_y} \left(\exp \left(-\langle \lambda, \tilde{X}_s^{B_r} \rangle \right) \right) \quad \text{for } y \in B_r \text{ and } s \in [0, T]. \quad (\text{A.8})$$

Since all the first partials of $\psi_\beta(x, \lambda)$ are continuous, it follows by [14, Theorem 5.2.2] that $v_\lambda(s, y) := \tilde{u}_\lambda^{B_r}(T - s, y)$ for $(s, y) \in (0, T) \times B_r$ is a solution of the following boundary problem:

$$\begin{cases} \frac{\partial v_\lambda}{\partial s} + Lv_\lambda = \psi_\beta(y, v_\lambda(s, y)), & (s, y) \in (0, T) \times B_r, \\ \lim_{(0, T) \times B_r \ni (s, y) \rightarrow z} v_\lambda(s, y) = \lambda, & z \in \partial((0, T) \times B_r). \end{cases}$$

Since $\psi_\beta(y, \lambda) \geq \psi(\lambda)$ for $y \in B_r$ and $\lambda \geq 0$, we have

$$\left\{ \begin{array}{l} \frac{\partial v_\lambda}{\partial s} + Lv_\lambda \geq \psi(v_\lambda), \quad (s, y) \in (0, T) \times B_r, \\ \lim_{(0, T) \times B_r \ni (s, y) \rightarrow z} v_\lambda(s, y) = \lambda, \quad z \in \partial((0, T) \times B_r). \end{array} \right.$$

By Lemma A.1, there is a solution $v^0(s, y)$ of the following problem:

$$\left\{ \begin{array}{l} \frac{\partial v^0}{\partial s} + Lv \leq \psi(v^0), \quad (s, y) \in (0, T) \times B_r, \\ v^0(s, x) \geq z_\psi, \quad (s, y) \in (0, T) \times B_r, \\ \lim_{(0, T) \times B_r \ni (s, y) \rightarrow z} v^0(s, y) = \infty, \quad z \in \mathcal{T}_{(0, T) \times B_r}. \end{array} \right.$$

where $\mathcal{T}_{(0, T) \times B_r} := ((0, T) \times \partial B_r) \cup (\{T\} \times \overline{B_r})$ is a total set of $\partial((0, T) \times B_r)$. By Lemma A.2, for any $\lambda > 0$,

$$v_\lambda(s, y) \leq v^0(s, y) \quad \text{for all } (s, y) \in (0, T) \times B_r.$$

Letting $\lambda \uparrow \infty$ in (A.8), we get that for any $t \in (0, T)$

$$-\log P_{\delta_x}(\tilde{X}_t^{B_r} = 0) = \lim_{\lambda \rightarrow \infty} v_\lambda(T - t, x) \leq v^0(T - t, x) < \infty.$$

Since $T > 0$ is arbitrary, we get (A.7) for all $t > 0$ and $r \in (0, \delta]$. \square

Note that condition (A.3) is stronger than $\int^\infty \psi(\lambda)^{-1} d\lambda < \infty$, which is usually called Grey's condition. Grey's condition is a necessary and sufficient condition for a CB process to become extinct in a finite time with positive probability. Lemma A.3 says that for a superdiffusion with spatially dependent branching mechanism, if the branching mechanism is locally dominated by a spatially independent branching mechanism which satisfies a condition stronger than the Grey's condition, then this superdiffusion become extinct in a finite time with positive probability.

Recall that $\alpha(x)$ is the non-negative bounded Borel measurable function in (2.1) and $E_+ = \{x \in E : \alpha(x) > 0\}$.

Proposition A.4. *For a (ξ, ψ_β) -superdiffusion, it holds that $E_+ \subset E_0$.*

Proof. Since all the first partials of ψ_β are continuous, α and β in ψ_β are continuous functions. Thus for any $x \in E_+$, there exists a neighborhood D of x such that $\sup_{y \in D} \beta(y) \leq \beta^* < \infty$ and $\inf_{y \in D} \alpha(y) \geq \alpha^* > 0$. We have

$$\psi_\beta(y, \lambda) \geq -\beta^* \lambda + \alpha^* \lambda^2 =: \psi^*(\lambda) \quad \text{for } y \in D \text{ and } \lambda \geq 0.$$

It is easy to verify that ψ^* satisfies (A.3). Hence $x \in E_0$ by Lemma A.3. \square

In the rest of this subsection, we assume Condition 1' holds. We will establish the existence of \mathbb{N}_x^* for all $x \in E_+$ under Condition 1'.

First we note that there exists a superdiffusion $((X_t)_{t \geq 0}; \mathbb{P}_\mu^*, \mu \in \mathcal{M}_F(E))$ with $\mathbb{P}_\mu^*(X_0 = \mu) = 1$ such that for all $\mu \in \mathcal{M}_F(E)$, $f \in \mathcal{B}_b^+(E)$ and $t \geq 0$,

$$\mathbb{P}_\mu^* \left[e^{-\langle f, X_t \rangle} \right] = e^{-\langle u_f^*(t, \cdot), \mu \rangle},$$

where $u_f^*(t, x)$ is the unique nonnegative locally bounded solution to the integral equation given by (2.17). The branching mechanism of this superdiffusion is $\psi_{\beta^*}^*(x, \lambda) := -\beta^*(x)\lambda + \psi_0^*(x, \lambda)$ where β^* and ψ_0^* are given in Proposition 2.2. Since w is only locally bounded on E , β^* is bounded from above but may not be bounded from below. Hence the branching mechanism $\psi_{\beta^*}^*(x, \lambda)$ does not satisfy the usual assumptions in Section 2.1. Nevertheless, one may consider the $(\xi^D, \psi_{\beta^*}^*)$ -superdiffusion in every bounded open domain D , where the

underlying spatial motion is killed upon hitting the boundary of D . Then by using an increasing sequence of compactly embedded domains to approximate E , the process (X, P_μ^*) can be defined as a distributional limit of these $(\xi^D, \psi_{\beta^*}^*)$ -superdiffusions. (see, for example, the argument before Theorem 2.4 in [16].) We remark that this method of construction may fail in general when the spatial motion has discontinuous sample paths since the process can potentially jump everywhere when it exits from the domain D .

Let E_0^* be the set of points in E where the Kuznetsov measure \mathbb{N}_x^* corresponding to the $(\xi, \psi_{\beta^*}^*)$ -superdiffusion exists. It follows that for every $x \in E_0^*$, every $t > 0$ and $f \in \mathcal{B}_b^+(E)$,

$$\mathbb{N}_x^* \left(1 - e^{-\langle f, X_t \rangle} \right) = u_f^*(t, x).$$

According to [12, Theorem I.1.1 and Theorem I.1.2], for any bounded open set $D \Subset E$ and $t \geq 0$, there exists a random measure \tilde{X}_t^{*D} concentrated on the boundary of $[0, t] \times D$, such that for every $\mu \in \mathcal{M}_F(E)$ and $\tilde{f} \in \mathcal{B}_b^+([0, t] \times E)$,

$$P_\mu^* \left[e^{-\langle \tilde{f}, \tilde{X}_t^{*D} \rangle} \right] = e^{-\langle \tilde{u}_f^{*D}(t, \cdot), \mu \rangle},$$

where $\tilde{u}_f^{*D}(t, x)$ is the unique nonnegative locally bounded solution to the following integral equation:

$$\tilde{u}_f^{*D}(t, x) = \Pi_x \left[\tilde{f}(t \wedge \tau_D, \xi_{t \wedge \tau_D}) \right] - \Pi_x \left[\int_0^{t \wedge \tau_D} \psi_{\beta^*}^* \left(\xi_s, \tilde{u}_f^{*D}(t-s, \xi_s) \right) ds \right]. \quad (\text{A.9})$$

Define $\tilde{w}(t, x) := w(x)$ for $(t, x) \in [0, \infty) \times E$. Using the local boundedness of w on E , we can deduce that for any bounded open set $D \Subset E$,

$$\tilde{w}(t, x) = \Pi_x \left(\tilde{w}(t \wedge \tau_D, \xi_{t \wedge \tau_D}) \right) - \Pi_x \left(\int_0^{t \wedge \tau_D} \psi_\beta(\xi_s, \tilde{w}(t-s, \xi_s)) ds \right). \quad (\text{A.10})$$

The next proposition shows that $\{\tilde{X}_t^{*D}; t \geq 0\}$ is a Doob's h -transformed process of $\{\tilde{X}_t^D; t \geq 0\}$ via the function \tilde{w} .

Proposition A.5. *Let $\mathcal{M}_F^w(E) := \{\mu \in \mathcal{M}_F(E) : \langle w, \mu \rangle < \infty\}$. Suppose $D \Subset E$ is a bounded open set and $\mu \in \mathcal{M}_F^w(E)$. Then for every $t \geq 0$ and $\tilde{f} \in \mathcal{B}_b^+([0, t] \times E)$,*

$$e^{-\langle w, \mu \rangle} P_\mu^* \left[e^{-\langle \tilde{f} + \tilde{w}, \tilde{X}_t^{*D} \rangle} \right] = P_\mu^* \left[e^{-\langle \tilde{f}, \tilde{X}_t^{*D} \rangle} \right]. \quad (\text{A.11})$$

Proof. Since the random measure \tilde{X}_t^{*D} is supported on the boundary of $[0, t] \times D$ and \tilde{w} is locally bounded on $[0, \infty) \times E$, it follows by (2.7) and (2.8) that

$$e^{-\langle w, \mu \rangle} P_\mu^* \left[\exp \left(-\langle \tilde{f} + \tilde{w}, \tilde{X}_t^{*D} \rangle \right) \right] = \exp \left(-\langle \tilde{u}_{\tilde{w} + \tilde{f}}^D(t, \cdot), \mu \rangle - w(\cdot), \mu \right),$$

where $\tilde{u}_{\tilde{w} + \tilde{f}}^D(t, x)$ is the unique nonnegative locally bounded solution to the following integral equation

$$\tilde{u}_{\tilde{w} + \tilde{f}}^D(t, x) = \Pi_x \left[(\tilde{w} + \tilde{f})(t \wedge \tau_D, \xi_{t \wedge \tau_D}) \right] - \Pi_x \left(\int_0^{t \wedge \tau_D} \psi_\beta(\xi_s, \tilde{u}_{\tilde{w} + \tilde{f}}^D(t-s, \xi_s)) ds \right) \quad (\text{A.12})$$

Using (A.12) and (A.10), it is straightforward to check that $\tilde{u}_f^{*D}(t, x) := \tilde{u}_{\tilde{w} + \tilde{f}}^D(t, x) - w(x)$ is the unique nonnegative locally bounded solution to (A.9). Thus we get (A.11). \square

Lemma A.6. *If $x \in E$ satisfies the condition of Lemma A.3, then $x \in E_0^*$.*

Proof. Based on the argument in the beginning of this subsection, it suffices to prove that there exists $\delta > 0$ such that

$$P_{\delta_x}^* (\tilde{X}_t^{*B} = 0) > 0 \quad \text{for all } t > 0 \text{ and } B = B(x, r) \text{ with } r \leq \delta.$$

We choose δ sufficiently small such that $B \subset D$, and $\psi_\beta(y, \lambda) \geq \psi(\lambda)$ for all $y \in B$ and $\lambda \geq 0$, where D and ψ satisfy the conditions of Lemma A.3. It follows from Proposition A.5 that

$$\begin{aligned} \mathbb{P}_{\delta_x}^*(\tilde{X}_t^{*B} = 0) &= \lim_{\lambda \rightarrow \infty} \mathbb{P}_{\delta_x}(e^{-\langle \lambda, \tilde{X}_t^{*B} \rangle}) \\ &= e^{-w(x)} \lim_{\lambda \rightarrow \infty} \mathbb{P}_{\delta_x}(e^{-\langle \tilde{w} + \lambda, \tilde{X}_t^B \rangle}) \\ &= e^{-w(x)} \lim_{\lambda \rightarrow \infty} e^{-\tilde{u}_{\tilde{w} + \lambda}^B(t, x)}, \end{aligned}$$

where $\tilde{u}_{\tilde{w} + \lambda}^B(t, x)$ is the unique nonnegative solution of (2.8) with initial condition $\tilde{w} + \lambda$. Then $v(s, y) := \tilde{u}_{\tilde{w} + \lambda}^B(t - s, y)$ for $(s, y) \in [0, t] \times B$, is a solution to the following boundary problem:

$$\left\{ \begin{array}{l} \frac{\partial v}{\partial s} + Lv = \psi_\beta(y, v(s, y)), \quad (s, y) \in (0, t) \times B \\ \lim_{(0, t) \times B \ni (s, y) \rightarrow z} v(t, y) = \tilde{w}(z) + \lambda, \quad z \in \partial((0, t) \times B). \end{array} \right.$$

Since $\psi_\beta(y, \lambda) \geq \psi(\lambda)$ for $y \in B$ and $\lambda \geq 0$, applying similar arguments as in the proof of Lemma A.3, we get $\lim_{\lambda \rightarrow \infty} \tilde{u}_{\tilde{w} + \lambda}^B(t, x) < \infty$. Therefore $\mathbb{P}_{\delta_x}^*(\tilde{X}_t^{*B} = 0) > 0$ for $t > 0$. Hence $x \in E_0^*$. \square

Proposition A.7. *For a (ξ, ψ_β) -superdiffusion that satisfies Condition 1', it holds that $E_+ \subset E_0^*$.*

Proof. This proposition follows from Lemma A.6 (instead of Lemma A.3) in the same way as the proof of Proposition A.4. We omit the details here. \square

A.2 Verifications of examples

Example 8.1: It is easy to check that Assumptions 1-4 are satisfied with $\lambda_1 = -\beta$, $h(x) \equiv 1$ and $w(x) \equiv z_\psi$. Then the h -transformed semigroup P_t^h is given by

$$P_t^h f(x) := \frac{e^{-\beta t}}{h(x)} \Pi_x [e^{\beta t} h(\xi_t) f(\xi_t)] = P_t f(x) \quad \text{for } f \in \mathcal{B}_b^+(\mathbb{R}^d).$$

This implies that the h -transformed process ξ^h is still an inward OU process with generate \mathcal{L} . It is known that the transition density of ξ^h with respect to m is given by

$$p^h(t, x, y) = (1 - e^{-2ct})^{-d/2} \exp\left(-\frac{c}{e^{2ct} - 1} (|x|^2 + |y|^2 - 2e^{ct} x \cdot y)\right) \quad \text{for } t > 0 \text{ and } x, y \in \mathbb{R}^d.$$

In view of this, one can easily check that ξ^h has the Feller property, that is, P_t^h maps $C_0(\mathbb{R}^d)$ to $C_0(\mathbb{R}^d)$ and $\lim_{t \rightarrow 0} \|P_t^h f - f\|_\infty = 0$ for all $f \in C_0(\mathbb{R}^d)$. It remains to show that Assumption 5 holds for this example. Let Z be the skeleton process. We need to show that for any $\mu \in \mathcal{M}_c(E)$, $\sigma > 0$ and $f \in \mathcal{B}^+(E)$ with $\frac{fw}{h}$ bounded,

$$\lim_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \langle f, Z_{n\sigma} \rangle = \langle f, wh \rangle W_\infty^{h/w}(Z) \quad \mathbb{P}_\mu\text{-a.s.} \quad (\text{A.13})$$

For $t \geq 0$, $Z_t = \sum_{i=1}^{N_0} Z_t^{i,0}$, where $N_0 = \langle 1, Z_0 \rangle$ and $Z^{i,0}$ denotes the independent subtree of the skeleton initiated by the i th particle at time 0. Recall that under \mathbb{P}_μ for $\mu \in \mathcal{M}_c(E)$, N_0 is a Poisson random variable with mean $\langle w, \mu \rangle$. Moreover, given Z_0 , $Z^{i,0}$ follows the same distribution as $(Z; \mathbb{P}_{\cdot, \delta_{z_i(0)}}$). Thus we have

$$\begin{aligned} & \mathbb{P}_\mu \left(\lim_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \langle f, Z_{n\sigma} \rangle = \langle f, wh \rangle W_\infty^{h/w}(Z) \right) \\ & \geq \mathbb{P}_\mu \left(\bigcap_{i=1}^{N_0} \left\{ \lim_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \langle f, Z_{n\sigma}^{i,0} \rangle = \langle f, wh \rangle W_\infty^{h/w}(Z^{i,0}) \right\} \right) \\ & = \mathbb{P}_\mu \left[\prod_{i=1}^{N_0} \mathbb{P}_{\cdot, \delta_{z_i(0)}} \left(\lim_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \langle f, Z_{n\sigma} \rangle = \langle f, wh \rangle W_\infty^{h/w}(Z) \right) \right]. \end{aligned}$$

Hence to prove (A.13), it suffices to prove that for every $x \in E$,

$$\mathbb{P}_{\cdot, \delta_x} \left(\lim_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \langle f, Z_{n\sigma} \rangle = \langle f, wh \rangle W_\infty^{h/w}(Z) \right) = 1. \quad (\text{A.14})$$

Sufficient conditions for (A.14) are given in [16] (see conditions (2.23)-(2.26), (2.34) and (2.35) there). In this example, conditions (2.23)-(2.26) in [16] hold for $\sigma_1 = \sigma_3 = p$, $\sigma_2 = 2$ and $\varphi_1(x) = \varphi_2(x) \equiv 1$, condition (2.34) holds for $a(t) = \sqrt{(\frac{-\lambda_1}{c} + \sigma)t}$ and condition (2.35) in [16] holds for $K = 1$. Hence we prove (A.13).

Example 8.2: Assumptions 1-4 are satisfied with $\lambda_1 = cd - \beta$, $h(x) = (\frac{c}{\pi})^{d/2} e^{-c|x|^2}$ and $w(x) \equiv z_\psi$. The transition density of ξ with respect to m is given by

$$p(t, x, y) = (e^{2ct} - 1)^{-d/2} \exp \left(-\frac{c}{1 - e^{-2ct}} (|x|^2 + |y|^2 - 2e^{-ct} x \cdot y) \right) \quad \text{for } t > 0 \text{ and } x, y \in \mathbb{R}^d.$$

The h -transformed process ξ^h is symmetric with respect to the measure $\tilde{m}(dx) = h^2 m(dx) = (\frac{c}{\pi})^{d/2} e^{-c|x|^2} dx$, and the transition density of ξ^h with respect to \tilde{m} is given by

$$p^h(t, x, y) = (1 - e^{-2ct})^{-d/2} \exp \left(-\frac{c}{e^{2ct} - 1} (|x|^2 + |y|^2 - 2e^{ct} x \cdot y) \right) \quad \text{for } t > 0 \text{ and } x, y \in \mathbb{R}^d.$$

This implies that ξ^h is an inward OU process on \mathbb{R}^d with infinitesimal generator $\mathcal{L}^h := \frac{1}{2}\Delta - cx \cdot \nabla$. Thus $\lim_{t \rightarrow 0} \|P_t^h f - f\|_\infty = 0$ for any $f \in C_0(\mathbb{R}^d)$. In view of Example 4.2 in [16], Assumption 5 is also satisfied.

Example 8.3: Suppose $\hat{\psi}_\beta(x, \lambda) := -\beta(x)\lambda + \alpha(x)\lambda^2$. Let \mathbb{X} be a (Y, ψ_β) -superdiffusion and $\hat{\mathbb{X}}$ be a $(Y, \hat{\psi}_\beta)$ -superdiffusion. For $x \in \mathbb{R}^d$, let $w_{\mathbb{X}}(x) := -\log P_{\delta_x}(\exists t \geq 0 : \langle 1, \mathbb{X}_t \rangle = 0)$ and $w_{\hat{\mathbb{X}}}(x) := -\log P_{\delta_x}(\exists t \geq 0 : \langle 1, \hat{\mathbb{X}}_t \rangle = 0)$.

We know from [18] that the function $w_{\hat{\mathbb{X}}}$ is continuous on \mathbb{R}^d and solves the equation $\mathcal{L}u - \hat{\psi}_\beta(x, u) = 0$ on \mathbb{R}^d . Since $\psi_\beta \geq \hat{\psi}_\beta$ pointwise, it follows by [16, Lemma 4.5] that $w_{\mathbb{X}} \leq w_{\hat{\mathbb{X}}}$ pointwise. Thus $w_{\mathbb{X}}$ is locally bounded on \mathbb{R}^d and hence is continuous on \mathbb{R}^d by [16, Lemma 2.1]. Recall that X is a (ξ, ψ_β) -superdiffusion where $\xi = Y^E$ is the subprocess of Y killing upon leaving E . We mentioned in Section 2.2 that one may think of X_t describing the mass in \mathbb{X}_t which historically avoids exiting E .

Since the function ρ in the generator is bounded between two positive constants, we know from [23] that ξ has a positive continuous transition density $p_E(t, x, y)$ with respect to m , and for each $T > 0$, there exist positive c_i , $i = 1, \dots, 4$ such that for every $(t, x, y) \in (0, T] \times E \times E$,

$$c_1 f_E(t, x, y) t^{-d/2} \exp \left(-\frac{c_2 |x - y|^2}{t} \right) \leq p_E(t, x, y) \leq c_3 f_E(t, x, y) t^{-d/2} \exp \left(-\frac{c_4 |x - y|^2}{t} \right), \quad (\text{A.15})$$

where $f_E(t, x, y) := \left(1 \wedge \frac{\delta_E(x)}{\sqrt{t}}\right) \left(1 \wedge \frac{\delta_E(y)}{\sqrt{t}}\right)$ and $\delta_E(x)$ denotes the Euclidean distance between x and the boundary of E . Since β is bounded, it follows that the Feynman-Kac semigroup P_t^β admits an integral kernel $p_E^\beta(t, x, y)$ which is positive, symmetric and continuous in (x, y) for each $t > 0$, and

$$e^{-\|\beta\|_\infty t} p_E(t, x, y) \leq p_E^\beta(t, x, y) \leq e^{\|\beta\|_\infty t} p_E(t, x, y) \quad \text{for all } x, y \in E \text{ and } t > 0.$$

Thus $p_E^\beta(t, x, y)$ satisfies the same two-sided estimates (A.15) with possibly different constants $c_i > 0$, $i = 4, \dots, 8$. By this estimate, $\int_{E \times E} p_E^\beta(t, x, y)^2 m(dx) m(dy) = \int_E p_E^\beta(2t, x, x) m(dx) < \infty$ for every $t \in (0, T]$. Thus P_t^β is a Hilbert-Schmidt operator in $L^2(E, m)$ and hence is compact. The infinitesimal generator of P_t^β is $\mathcal{L}^{(\beta)} := (\mathcal{L} + \beta)|_E$ with zero Dirichlet boundary condition. We use $\sigma(\mathcal{L}^{(\beta)})$ to denote the spectrum set of $\mathcal{L}^{(\beta)}$. It then follows from Jentzch's theorem that $\lambda_1 := \inf\{-\lambda : \lambda \in \sigma(\mathcal{L}^{(\beta)})\}$ is a simple eigenvalue and a corresponding eigenfunction h can be chosen to be nonnegative with $\int_E h(x)^2 m(dx) = 1$. We assume $\lambda_1 < 0$. Since $h(x) = e^{\lambda_1 t} \int_E p_E^\beta(t, x, y) h(y) m(dy)$, h is continuous and positive on E . Moreover, by the estimate (A.15), we have

$$c_9 (1 \wedge \delta_E(x)) \leq h(x) \leq c_{10} (1 \wedge \delta_E(x)) \quad \text{for all } x \in E. \quad (\text{A.16})$$

Here c_9, c_{10} are positive constants independent of x . Therefore, Assumptions 2-3 hold.

Let $w(x) := -\log P_{\delta_x}(\exists t \geq 0 : \langle 1, X_t \rangle = 0)$. Since h is bounded on E , it is easy to see that condition (2.27) (or, equivalently, Assumption 4(i)) holds. Thus by Theorem 2.9 and Remark 2.10, $P_{\delta_x}(W_\infty^h(X) > 0) > 0$ for every $x \in E$. It follows that

$$w(x) \geq -\log \left(1 - P_{\delta_x} \left(\limsup_{t \rightarrow \infty} \langle 1, X_t \rangle > 0 \right) \right) \geq -\log \left(1 - P_{\delta_x} (W_\infty^h(X) > 0) \right) > 0 \quad \text{for } x \in E.$$

On the other hand, since X_t describes only part of the mass in \mathbb{X}_t , we have $P_{\delta_x}(\exists t \geq 0 : \langle 1, X_t \rangle = 0) \geq P_{\delta_x}(\exists t \geq 0 : \langle 1, \mathbb{X}_t \rangle = 0)$ and hence $w(x) \leq w_{\mathbb{X}}(x)$ on E . This together with the continuity of $w_{\mathbb{X}}$ on \mathbb{R}^d implies that w is bounded on E and hence is continuous on E by [16, Lemma 2.1]. This shows that Condition 1 holds, and, consequently, Assumption 1 is satisfied.

We now show that Assumption 4(ii) holds for this example. By condition (8.1) and the boundedness of w , one can easily prove that $\frac{\psi_\beta(x, w(x))}{w(x)} = -\beta(x) + \alpha(x)w(x) + \int_{(0, \infty)} \frac{e^{-w(x)y} - 1 + w(x)y}{w(x)} \pi(x, dy)$ is a bounded function on E . Let $\{D_n : n \geq 1\}$ be a sequence of bounded domains with smooth boundaries such that $D_n \Subset D_{n+1} \Subset E$ for $n \geq 1$ and $\bigcup_{n=1}^\infty D_n = E$. We know from the argument in the beginning of Section 5 that for $t > 0$, $x \in E$ and n sufficiently large so that $x \in D_n$,

$$w(x) = \Pi_x \left[w(\xi_{t \wedge \tau_{D_n}}) \exp \left(- \int_0^{t \wedge \tau_{D_n}} \frac{\psi_\beta(\xi_s, w(\xi_s))}{w(\xi_s)} ds \right) \right].$$

Consequently,

$$\begin{aligned} w(x) &\geq \exp \left(-t \sup_{y \in E} \frac{\psi_\beta(y, w(y))}{w(y)} \right) \Pi_x (w(\xi_{t \wedge \tau_{D_n}})) \\ &= e^{-c_{13}t} (\Pi_x [w(\xi_t); t < \tau_{D_n}] + \Pi_x [w(\xi_{\tau_{D_n}}); t \geq \tau_{D_n}]) \\ &\geq e^{-c_{13}t} \Pi_x [w(\xi_t); t < \tau_{D_n}] = e^{-c_{13}t} \Pi_x [w(Y_t); t < \tau_{D_n}]. \end{aligned}$$

Thus by letting $n \rightarrow \infty$, we get $w(x) \geq e^{-c_{13}t} \Pi_x [w(Y_t); t < \tau_E] = e^{-c_{13}t} \Pi_x [w(Y_t^E)]$. Using this and the heat kernel estimates in (A.15), we have for $x \in E$

$$\begin{aligned} w(x) &\geq e^{-c_{13}t} \Pi_x [w(Y_1^E)] \\ &= e^{-c_{13}} \int_E p_E(1, x, y) w(y) m(dy) \\ &\geq c_1 e^{-c_{13}} \int_E (1 \wedge \delta_E(x)) (1 \wedge \delta_E(y)) e^{-c_2|x-y|^2} w(y) m(dy) \\ &\geq c_1 e^{-c_{13} - c_2 \text{diam}(E)^2} (1 \wedge \delta_E(x)) \int_E (1 \wedge \delta_E(y)) w(y) m(dy) \\ &\geq c_{14} (1 \wedge \delta_E(x)). \end{aligned} \tag{A.17}$$

Here $c_{14} > 0$ is constant and the last inequality comes from the fact that $(1 \wedge \delta_E(y))w(y)$ is positive everywhere on E . By (A.17) and (A.16), we have for $x \in E$,

$$\begin{aligned} \int_{(0, \infty)} r^2 e^{-w(x)r} \pi(x, dr) &\leq \int_{(0, \infty)} r^2 e^{-c_{14}(1 \wedge \delta_E(x))r} \pi(x, dr) \\ &\leq \int_{(0, \infty)} r^2 e^{-c_{15}h(x)r} \pi(x, dr) \\ &= \frac{1}{h(x)} \int_{(0, \infty)} r \log^* r \left(\frac{rh(x)}{\log^*(rh(x))} e^{-c_{15}h(x)r} \right) \frac{\log^*(rh(x))}{\log^* r} \pi(x, dr) \\ &\leq \frac{1}{h(x)} \int_{(0, \infty)} r \log^* r \left(\frac{rh(x)}{\log^*(rh(x))} e^{-c_{15}h(x)r} \right) \frac{\log^*(r \|h\|_\infty)}{\log^* r} \pi(x, dr), \end{aligned}$$

where c_{15} is a positive constant. It then follows from condition (8.1), and the fact that functions $y \mapsto \frac{y}{\log^* y} e^{-c_{15}y}$ and $y \mapsto \frac{\log^*(y\|h\|_\infty)}{\log^* y}$ are bounded on $(0, \infty)$ that $\int_{(0, \infty)} r^2 e^{-w(x)r} \pi(x, dr) \leq c_{16} h(x)^{-1}$ on E . Immediately we get $\langle \left(\int_{(0, \infty)} r^2 e^{-w(\cdot)r} \pi(\cdot, dr) \right)^2, 1 \wedge h^4 \rangle \leq c_{16}^2 \int_E (h(x)^{-2} \wedge h(x)^2) m(dx) < \infty$. Hence Assumption 4(ii) holds.

We next show Assumption 6 holds. Let P_t^h be the h -transformed semigroup from P_t^β given by (2.25). P_t^h admits an integral kernel $p_E^h(t, x, y)$ with respect to the measure $\tilde{m}(dx) := h(x)^2 m(dx)$, which is related to $p_E^\beta(t, x, y)$ by

$$p_E^h(t, x, y) = e^{\lambda_1 t} \frac{p_E^\beta(t, x, y)}{h(x)h(y)} \quad \text{for } x, y \in E \text{ and } t \geq 0.$$

Define $\tilde{a}_t(x) := p_E^h(t, x, x)$ for $x \in E$ and $t > 0$. Clearly by (A.15) and (A.16), we have $\sup_{x \in E} \tilde{a}_t(x) < \infty$ for every $t > 0$. Let $e_\beta(t) := \int_0^t \beta(\xi_s) ds$. Suppose $f \in C_0(E)$. Then for any given $\varepsilon > 0$, there is $\delta > 0$ so that $|f(x) - f(y)| < \varepsilon$ whenever $|x - y| < \delta$. By the two-sided estimate of $p_E^\beta(t, x, y)$, for sufficiently small $t \in (0, 1]$,

$$\begin{aligned} \sup_{x \in E} |P_t^h f(x) - f(x)| &= \sup_{x \in E} \frac{|e^{\lambda_1 t} P_t^\beta(hf)(x) - h(x)f(x)|}{h(x)} \\ &= \sup_{x \in E} e^{\lambda_1 t} \frac{|\Pi_x [e_\beta(t)h(\xi_t)(f(\xi_t) - f(\xi_0))]|}{h(x)} \\ &\leq \varepsilon + \sup_{x \in E} e^{\lambda_1 t} \frac{|\Pi_x [e_\beta(t)h(\xi_t)(f(\xi_t) - f(\xi_0)); |\xi_t - \xi_0| \geq \delta]|}{h(x)} \\ &\leq \varepsilon + e^{(\lambda_1 + \|\beta\|_\infty)t} \|h\|_\infty \|f\|_\infty \sup_{x \in E} \frac{\Pi_x (|\xi_t - \xi_0| \geq \delta)}{h(x)} \\ &\leq \varepsilon + c_{11} \sup_{x \in E} \frac{\delta_E(x)}{1 \wedge \delta_E(x)} \int_{y \in E: |y-x| \geq \delta} t^{-(d+1)/2} \exp(-c_4|x-y|^2/t) dy \\ &\leq \varepsilon + c_{12}(1 + \text{diam}(E)) \int_{|z| \geq \delta} t^{-(d+1)/2} e^{-c_4|z|^2/t} dz \\ &= \varepsilon + c_{12}(1 + \text{diam}(E)) t^{-1/2} \int_{\delta t^{-1/2}}^\infty r^{d-1} e^{-c_4 r^2} dr. \end{aligned}$$

It follows that $\lim_{t \rightarrow 0} \|P_t^h f - f\|_\infty = 0$ for all $f \in C_0(E)$.

It remains to prove that Assumption 5 holds. Fix $\phi \in \mathcal{B}_b^+(E)$, $\mu \in \mathcal{M}_c(E)$ and $\sigma > 0$. For $m, n \in \mathbb{N}$, we have

$$e^{\lambda_1(m+n)\sigma} \left\langle \frac{h}{w} \phi, Z_{(m+n)\sigma} \right\rangle - \langle \phi, h^2 \rangle W_\infty^{h/w}(Z) = I(m, n) + II(m, n) + III(n), \quad (\text{A.18})$$

where $I(m, n) := e^{\lambda_1(m+n)\sigma} \left\langle \frac{h}{w} \phi, Z_{(m+n)\sigma} \right\rangle - \mathbb{P}_\mu \left(e^{\lambda_1(m+n)\sigma} \left\langle \frac{h}{w} \phi, Z_{(m+n)\sigma} \right\rangle \middle| \mathcal{F}_{n\sigma} \right)$,

$$II(m, n) := \mathbb{P}_\mu \left(e^{\lambda_1(m+n)\sigma} \left\langle \frac{h}{w} \phi, Z_{(m+n)\sigma} \right\rangle \middle| \mathcal{F}_{n\sigma} \right) - \langle \phi, h^2 \rangle W_{n\sigma}^{h/w}(Z),$$

and $III(n) := \langle \phi, h^2 \rangle \left(W_{n\sigma}^{h/w}(Z) - W_\infty^{h/w}(Z) \right)$. Note that by the Markov property of Z ,

$$\begin{aligned} \mathbb{P}_\mu \left(e^{\lambda_1 n \sigma} \left\langle \frac{h}{w} \phi, Z_{(m+n)\sigma} \right\rangle \middle| \mathcal{F}_{n\sigma} \right) &= e^{\lambda_1(m+n)\sigma} \mathbb{P}_{\cdot, Z_{n\sigma}} \left(\left\langle \frac{h}{w} \phi, Z_{m\sigma} \right\rangle \right) \\ &= e^{\lambda_1(m+n)\sigma} \left\langle \frac{1}{w} P_{m\sigma}^\beta(h\phi), Z_{n\sigma} \right\rangle = e^{\lambda_1 n \sigma} \left\langle \frac{h}{w} P_{m\sigma}^h \phi, Z_{n\sigma} \right\rangle. \end{aligned}$$

Thus $II(m, n) = e^{\lambda_1 n \sigma} \left\langle \frac{h}{w} P_{m\sigma}^h g, Z_{n\sigma} \right\rangle$, where $g(x) := \phi(x) - \langle \phi, h^2 \rangle$. Since $\langle g, h^2 \rangle = 0$, $|P_{m\sigma}^h g(x)| \leq e^{-\lambda_h(m\sigma - \frac{1}{2})} \tilde{a}_1(x)^{1/2} \|g\|_{L^2(E, h^2 m)}$ for $m\sigma > 1/2$. Here $\lambda_h > 0$ denotes the spectral gap in $\sigma(\mathcal{L}^{(\beta)})$. Thus

we have for $m\sigma > 1/2$

$$|II(m, n)| = \left| e^{\lambda_1 n \sigma} \left\langle \frac{h}{w} P_{m\sigma}^h g, Z_{n\sigma} \right\rangle \right| \leq c_{14} e^{-\lambda_h m \sigma} \sup_{x \in E} \tilde{a}_1(x)^{1/2} W_{n\sigma}^{h/w}(Z).$$

It is shown in the proof of the equivalence between Assumption 5 and Assumption 5' that for every $m \in \mathbb{N}$, $\lim_{n \rightarrow \infty} I(m, n) = 0$ \mathbb{P}_μ -a.s. Thus by letting $n \rightarrow \infty$ and then $m \rightarrow \infty$ in (A.18), we obtain that

$$\lim_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \left\langle \frac{h}{w} \phi, Z_{n\sigma} \right\rangle - \langle \phi, h^2 \rangle W^{h/w}(Z) = 0 \quad \mathbb{P}_\mu\text{-a.s.}$$

Example 8.4: Let $\lambda_h := \lambda_2 - \lambda_1$ be the spectral gap in $\sigma(\mathcal{L}^{(\beta)})$, where $\lambda_2 := \inf \{ \lambda \in \sigma(-\mathcal{L}^{(\beta)}) : \lambda \neq \lambda_1 \}$. Since $P_t^\beta h(x) = e^{-\lambda_1 t} h(x)$, it follows by property (ii) and Hölder inequality that $h \in L^4(E, m)$. Let $g_0(\theta) := \log^* \theta / \theta$ for $\theta \in (0, +\infty)$. Then

$$\begin{aligned} \left\langle \int_{(0, +\infty)} r \log^*(rh(\cdot)) \pi(\cdot, dr), h^2 \right\rangle &= \left\langle \int_{(0, +\infty)} g_0(rh(\cdot)) r^2 \pi(\cdot, dr), h^3 \right\rangle \\ &\leq \|g_0\|_\infty \left\langle \int_{(0, +\infty)} r^2 \pi(\cdot, dr), h^3 \right\rangle \\ &< +\infty. \end{aligned}$$

The last inequality comes from the fact that $h \in L^4(E, m)$ and condition (8.2). Thus we have by Theorem 2.9 and Remark 2.10 that $P_{\delta_x}(W_\infty^h(X) > 0) > 0$ for each $x \in E$. Hence

$$w(x) \geq -\log \left(1 - P_{\delta_x} \left(\limsup_{t \rightarrow +\infty} \langle 1, X_t \rangle > 0 \right) \right) \geq -\log (1 - P_{\delta_x} (W_\infty^h(X) > 0)) > 0.$$

In view of Remark 2.7, $w(x)$ is a bounded function on E under our assumptions. Using the boundedness of w and (8.2), it is easy to verify that Assumptions 1-4 and Assumption 6 are satisfied by this example. Next we will show that Assumption 5' is also satisfied, that is, for all $\mu \in \mathcal{M}_c(E)$, $\phi \in \mathcal{B}_b^+(E)$, $\sigma > 0$ and some $m \in \mathbb{N}$,

$$\lim_{n \rightarrow +\infty} e^{\lambda_1 n \sigma} \left\langle \frac{h}{w} P_{m\sigma}^h \phi, Z_{n\sigma} \right\rangle = \langle \phi, h^2 \rangle W_\infty^{h/w}(Z) \quad \mathbb{P}_\mu\text{-a.s.} \quad (\text{A.19})$$

It is showed in the proof of Lemma 7.4 that

$$e^{\lambda_1 n \sigma} \left\langle \frac{h}{w} P_{m\sigma}^h \phi, Z_{n\sigma} \right\rangle = e^{\lambda_1 (m+n)\sigma} \sum_{i=1}^{N_{n\sigma}} \mathbb{P}_\mu (\langle \phi h, I_{m\sigma}^{i, n\sigma} \rangle | \mathcal{F}_{n\sigma}) + e^{\lambda_1 n \sigma} \left\langle \frac{h}{w} \theta_{\phi h}^*(m\sigma, \cdot), Z_{n\sigma} \right\rangle.$$

Thus by Lemma 5.2, Lemma 7.3 and Theorem 2.11, under Assumptions 1-3 and Assumption 4(i), (A.19) is equivalent to that

$$\lim_{n \rightarrow +\infty} e^{\lambda_1 (m+n)\sigma} \sum_{i=1}^{N_{n\sigma}} \langle \phi h, I_{m\sigma}^{i, n\sigma} \rangle = \langle \phi, h^2 \rangle W_\infty^h(X) \quad \mathbb{P}_\mu\text{-a.s.} \quad (\text{A.20})$$

Since $e^{\lambda_1 (m+n)\sigma} \langle \phi h, X_{(m+n)\sigma} \rangle \geq e^{\lambda_1 (m+n)\sigma} \sum_{i=1}^{N_{n\sigma}} \langle \phi h, I_{m\sigma}^{i, n\sigma} \rangle$ and $\phi \in \mathcal{B}_b^+(E)$, (A.20) (or equivalently (A.19)) is equivalent to

$$\lim_{n \rightarrow +\infty} e^{\lambda_1 n \sigma} \langle \phi h, X_{n\sigma} \rangle = \langle \phi, h^2 \rangle W_\infty^h(X) \quad \mathbb{P}_\mu\text{-a.s.} \quad (\text{A.21})$$

Fix $\phi \in \mathcal{B}_b^+(E)$ and $\mu \in \mathcal{M}_c(E)$. Let $g(x) := \phi(x) - \langle \phi, h^2 \rangle$ for $x \in E$. We have by (2.6) that for $t > 0$,

$$\begin{aligned} \mathbb{P}_\mu \left[(e^{\lambda_1 t} \langle gh, X_t \rangle)^2 \right] &= \langle P_t^h g, h\mu \rangle^2 + \int_0^t e^{\lambda_1 s} \langle P_s^h \left[\left(2\alpha + \int_{(0, +\infty)} y^2 \pi(\cdot, dy) \right) h (P_{t-s}^h g)^2 \right], h\mu \rangle ds \\ &=: I(t) + II(t). \end{aligned}$$

Since $g \in L^2(E, \tilde{m})$ and $\langle g, h^2 \rangle = 0$, we have by (3.6) for $r > t_0/2$ and $x \in E$,

$$|P_\lambda^h g(x)| \leq e^{-\lambda_h(r - \frac{t_0}{2})} \tilde{a}_{t_0}(x)^{1/2} \|g\|_{L^2(E, \tilde{m})} =: c_1 e^{-\lambda_h r} \tilde{a}_{t_0}(x)^{1/2}. \quad (\text{A.22})$$

Thus $I(t) \leq c_2 e^{-2\lambda_h t}$ for all $t > t_0/2$ and some $c_2 > 0$. On the other hand, for $r \in (0, t_0/2]$ and $x \in E$,

$$|P_\lambda^h g(x)| \leq \|g\|_\infty \leq \|g\|_\infty e^{\lambda_h(\frac{t_0}{2} - r)} =: c_3 e^{-\lambda_h r}. \quad (\text{A.23})$$

Let $\varepsilon \in (0, -\lambda_1 \wedge 2\lambda_h)$, we have by (A.22) and (A.23) that

$$\begin{aligned} II(t) &\leq \|2\alpha + \int_{(0, +\infty)} y^2 \pi(\cdot, dy)\|_\infty \int_0^t e^{\lambda_1 s} \langle P_s^h (h (P_{t-s}^h g)^2), h\mu \rangle ds \\ &\leq c_4 \int_0^t e^{\lambda_1 s - 2\lambda_h(t-s)} \langle P_s^h (h(1 \vee \tilde{a}_{t_0})), h\mu \rangle ds \\ &\leq c_4 e^{-\varepsilon t} \int_0^{+\infty} e^{(\lambda_1 + \varepsilon)s} \langle P_s^h (h(1 \vee \tilde{a}_{t_0})), h\mu \rangle ds. \end{aligned} \quad (\text{A.24})$$

Since $h \in L^4(E, m)$, it follows by property (ii) that $h(1 \vee \tilde{a}_{t_0}) \in L^2(E, \tilde{m})$. Thus by (3.6), $\langle P_s^h (h(1 \vee \tilde{a}_{t_0})), h\mu \rangle$ is bounded from above for s sufficiently large. Therefore the integral in the right hand side of (A.24) is finite. It implies that $\sum_{n=1}^{+\infty} \mathbb{P}_\mu \left[(e^{\lambda_1 n \sigma} \langle gh, X_{n\sigma} \rangle)^2 \right] < +\infty$, and hence we obtain (A.21) by Borel-Cantelli Lemma.

Example 8.5: By a similar argument as that for [3, IV.5], we have

$$h(x) \geq c_0 |x|^{-d-\alpha} \text{ for } |x| \geq 1, \quad (\text{A.25})$$

for some positive constant c_0 . Let λ_2 be the second bottom of the spectrum of $\sigma(\mathcal{E}^{(\beta)})$, that is $\lambda_2 := \inf\{\mathcal{E}^{(\beta)}(u, u) : u \in \mathcal{F} \text{ with } \int_{\mathbb{R}^d} u(x)h(x)dx = 0 \text{ and } \int_{\mathbb{R}^d} u(x)^2 dx = 1\}$. Then the spectral gap $\lambda_h := \lambda_2 - \lambda_1 > 0$. Recall that the h -transformed semigroup P_t^h is an \tilde{m} -symmetric semigroup with $\tilde{m}(dx) = h(x)^2 dx$. P_t^h admits an integral kernel $p^h(t, x, y)$, given by (3.5), with respect to the measure $\tilde{m}(dx)$. Let $p^\beta(t, x, y)$ be the integral kernel of P_t^β with respect to the Lebesgue measure, which satisfies the estimates in (2.22). For any $f \in C_c(\mathbb{R}^d)$, $t > 0$ and $x \in \mathbb{R}^d$, we have by (8.3) and (2.22) that

$$\begin{aligned} |P_t^h f(x) - f(x)| &\leq \int_{\mathbb{R}^d} p^h(t, x, y) |f(y) - f(x)| \tilde{m}(dy) \\ &= \frac{e^{\lambda_1 t}}{h(x)} \int_{\mathbb{R}^d} p^\beta(t, x, y) h(y) |f(y) - f(x)| dy \\ &\leq c_1 \frac{e^{(\lambda_1 + \|\beta\|_\infty)t}}{h(x)} \int_{\mathbb{R}^d} \left(t^{-d/\alpha} \wedge \frac{t}{|x-y|^{d+\alpha}} \right) h(y) |f(y) - f(x)| dy \end{aligned} \quad (\text{A.26})$$

Let $f_t(x) := \frac{1}{h(x)} \int_{\mathbb{R}^d} \left(t^{-d/\alpha} \wedge \frac{t}{|x-y|^{d+\alpha}} \right) h(y) |f(y) - f(x)| dy$. Suppose $\text{supp}(f) \subset B(0, R)$ for some $R > 1$. For $x \in B(0, 2R)$ and $z \in \mathbb{R}^d$, $h(z)/h(x) \leq \|h\|_\infty / \inf_{y \in B(0, 2R)} h(y) < \infty$, and we have

$$\begin{aligned} f_t(x) &\leq c_2 \int_{\mathbb{R}^d} \left(t^{-d/\alpha} \wedge \frac{t}{|x-y|^{d+\alpha}} \right) |f(y) - f(x)| dy \\ &= c_2 \int_{\mathbb{R}^d} \left(t^{-d/\alpha} \wedge \frac{t}{|z|^{d+\alpha}} \right) |f(x+z) - f(x)| dz. \end{aligned} \quad (\text{A.27})$$

Since $f \in C_c(\mathbb{R}^d)$ is uniformly continuous on \mathbb{R}^d , for any $\varepsilon > 0$, there exists $\delta > 0$, such that $|f(z_1) - f(z_2)| \leq \varepsilon$ whenever $|z_1 - z_2| < \delta$. Thus by (A.27),

$$f_t(x) \leq c_2 \varepsilon \int_{|z| < \delta} t^{-d/\alpha} \wedge \frac{t}{|z|^{d+\alpha}} dz + 2c_2 \|f\|_\infty \int_{|z| \geq \delta} t^{-d/\alpha} \wedge \frac{t}{|z|^{d+\alpha}} dz$$

$$= c_2 \varepsilon \int_{|u| < \delta t^{-1/\alpha}} 1 \wedge \frac{1}{|u|^{d+\alpha}} du + 2c_2 \|f\|_\infty \int_{|u| \geq \delta t^{-1/\alpha}} 1 \wedge \frac{1}{|u|^{d+\alpha}} du \quad (\text{A.28})$$

Since $\int_{\mathbb{R}^d} 1 \wedge \frac{1}{|u|^{d+\alpha}} du < \infty$, by letting $t \rightarrow 0$ and $\varepsilon \rightarrow 0$ in (A.28), we get $\sup_{x \in B(0, 2R)} f_t(x) \rightarrow 0$. On the other hand, for $x \notin B(0, 2R)$, by the fact $\text{supp}(f) \subset B(0, R)$, the boundedness of h and (A.25), we have

$$\begin{aligned} f_t(x) &= \frac{1}{h(x)} \int_{|y| \leq R} \left(t^{-d/\alpha} \wedge \frac{t}{|x-y|^{d+\alpha}} \right) h(y) |f(y)| dy \\ &\leq c_3 \int_{|y| \leq R} \left(t^{-d/\alpha} \wedge \frac{t}{|x-y|^{d+\alpha}} \right) |x|^{d+\alpha} dy \\ &\leq c_3 \int_{|y| \leq R} \frac{t|x|^{d+\alpha}}{(|x|-|y|)^{d+\alpha}} dy \\ &\leq c_3 \int_{|y| \leq R} \frac{t|x|^{d+\alpha}}{(|x|-R)^{d+\alpha}} dy \\ &\leq 2^{d+\alpha} c_3 t. \end{aligned}$$

Thus $\sup_{x \notin B(0, 2R)} f_t(x) \rightarrow 0$ as $t \rightarrow 0$. Hence by (A.26) we conclude that

$$\lim_{t \rightarrow 0} \|P_t^h f - f\|_\infty = 0 \quad (\text{A.29})$$

for all $f \in C_c(\mathbb{R}^d)$. Since $C_c(\mathbb{R}^d)$ is dense in $(C_0(\mathbb{R}^d), \|\cdot\|_\infty)$, (A.29) is true for all $f \in C_0(\mathbb{R}^d)$.

Recall that $w(x) = -\log P_{\delta_x}(\exists t \geq 0, \langle 1, X_t \rangle = 0)$. The argument in Remark 2.7 shows that $w(x)$ is bounded on E and so Condition 1 is satisfied. Let $W_t^h(X) := e^{\lambda_1 t} \langle h, X_t \rangle$. Then $W_t^h(X)$ is a nonnegative P_μ -martingale with respect to $\mathcal{F}_t := \sigma\{X_s : s \in [0, t]\}$ for all $\mu \in \mathcal{M}_F(E)$. Let $W_\infty^h(X) := \lim_{t \rightarrow \infty} W_t^h(X)$. Note that by (2.6),

$$\begin{aligned} P_{\delta_x}(W_t^h(X)^2) &= h(x)^2 + e^{2\lambda_1 t} \int_0^t P_s^\beta \left[\hat{\alpha} \left(P_{t-s}^\beta h \right)^2 \right] (x) ds \\ &= h(x)^2 + \int_0^t e^{2\lambda_1 s} P_s^\beta [\hat{\alpha} h^2] (x) ds \\ &\leq h(x)^2 + \|\hat{\alpha} h\|_\infty \int_0^t e^{2\lambda_1 s} P_s^\beta h(x) ds \\ &= h(x)^2 + \|\hat{\alpha} h\|_\infty h(x) \int_0^t e^{\lambda_1 s} ds \\ &\leq h(x)^2 + c_4 h(x). \end{aligned} \quad (\text{A.30})$$

Here $\hat{\alpha}(x) := 2\alpha(x) + \int_{(0, \infty)} y^2 \pi(x, dy)$ for $x \in E$ and c_4 is a positive constant independent of t . Thus for any $\mu \in \mathcal{M}_F^h(E)$, $\{W_t^h(X) : t \geq 0\}$ is an L^2 -bounded nonnegative martingale and hence $W_t^h(X)$ converges to $W_\infty^h(X)$ P_μ -a.s. and in $L^2(P_\mu)$. In particular $P_\mu(W_\infty^h(X) > 0) > 0$. Thus $P_{\delta_x}(\exists t > 0, \langle 1, X_t \rangle = 0) \leq 1 - P_{\delta_x}(W_\infty^h(X) > 0) < 1$, and so $w(x) > 0$ for all $x \in \mathbb{R}^d$. Furthermore, By Cauchy-Schwartz inequality and (A.30), we have

$$P_{\delta_x}(W_\infty^h(X) > 0) \geq \frac{(P_{\delta_x}[W_\infty^h(X)])^2}{P_{\delta_x}[W_\infty^h(X)^2]} = \frac{h(x)^2}{\lim_{t \rightarrow \infty} P_{\delta_x}[W_t^h(X)^2]} \geq \frac{h(x)}{h(x) + c_4}.$$

Thus we get

$$w(x) \geq -\log(1 - P_{\delta_x}(W_\infty^h(X) > 0)) \geq \log(h(x) + c_4) - \log c_4.$$

Using this, (A.25) and the fact that h is bounded away from 0 and ∞ on compact sets, we conclude that the function $h(x)/w(x)$ is bounded from above on \mathbb{R}^d . We see from the above arguments that Assumptions 1-4 and Assumption 6 are satisfied by this example.

Finally we will show that Assumption 5 is also satisfied. Let Z be the skeleton process. We need to show that for all $\mu \in \mathcal{M}_c(E)$, $\sigma > 0$ and $f \in \mathcal{B}^+(E)$ with $\frac{fw}{h}$ bounded,

$$\lim_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \langle f, Z_{n\sigma} \rangle = \langle f, wh \rangle W_\infty^{h/w}(Z) \quad \mathbb{P}_\mu\text{-a.s.} \quad (\text{A.31})$$

Fix $f \in \mathcal{B}^+(E)$ with fw/h bounded. Let $g(x) := f(x) - \langle f, wh \rangle \frac{h}{w}(x) = \left(\frac{fw}{h}(x) - \langle f, wh \rangle \right) \frac{h}{w}(x)$ for $x \in E$. Through the same argument as in Example 8.1, to prove (A.31), it suffices to prove that for every $x \in E$,

$$\mathbb{P}_{\cdot, \delta_x} \left(\lim_{n \rightarrow \infty} e^{\lambda_1 n \sigma} \langle g, Z_{n\sigma} \rangle = 0 \right) = 1. \quad (\text{A.32})$$

We observe that $g, \frac{gw}{h}$ are bounded functions on \mathbb{R}^d by the boundedness of $\frac{h}{w}$ and $\frac{fw}{h}$. For every $x \in \mathbb{R}^d$,

$$\mathbb{P}_{\cdot, \delta_x} \left[\left(e^{\lambda_1 t} \langle g, Z_t \rangle \right)^2 \right] = \frac{h(x)}{w(x)} \left(I(t, x) + II(t, x) \right),$$

where $I(t, x) := e^{\lambda_1 t} P_t^h \left(\frac{w}{h} g^2 \right) (x)$, $II(t, x) := \int_0^t e^{\lambda_1 s} P_s^h \left[(2\alpha + b) \frac{h}{w} P_{t-s}^h \left(\frac{w}{h} g \right)^2 \right] (x) ds$. For I , we have

$$I(t, x) \leq \left\| \frac{w}{h} g \right\|_\infty \|g\|_\infty e^{\lambda_1 t}. \quad (\text{A.33})$$

For II , we have

$$II(t, x) \leq \|2\alpha + b\|_\infty \left\| \frac{h}{w} \right\|_\infty \left\| \frac{w}{h} g \right\|_\infty \int_0^t e^{\lambda_1 s} P_s^h \left[\left| P_{t-s}^h \left(\frac{w}{h} g \right) \right| \right] (x) ds. \quad (\text{A.34})$$

Since $\langle \frac{w}{h} g, h^2 \rangle = 0$, by (2.26) and Hölder inequality for any $t > s > 0$

$$\begin{aligned} P_s^h \left[\left| P_{t-s}^h \left(\frac{w}{h} g \right) \right| \right] (x) &= \int_{\mathbb{R}^d} p^h(s, x, y) \left| P_{t-s}^h \left(\frac{w}{h} g \right) \right| \tilde{m}(dy) \\ &\leq \left(\int_{\mathbb{R}^d} p^h(s, x, y)^2 \tilde{m}(dy) \right)^{1/2} \|P_{t-s}^h \left(\frac{w}{h} g \right)\|_{L^2(\mathbb{R}^d, \tilde{m})} \\ &\leq e^{-\lambda_h(t-s)} p^h(2s, x, x)^{1/2} \left\| \frac{w}{h} g \right\|_{L^2(\mathbb{R}^d, \tilde{m})} \end{aligned} \quad (\text{A.35})$$

Let $\varepsilon \in (0, -\lambda_1 \wedge \lambda_h)$. Note that by (3.6), for each x , $p^h(s, x, x)$ is bounded from above when s is sufficiently large. This together with (A.34) and (A.35) yield that for every $x \in \mathbb{R}^d$,

$$II(t, x) \leq c_5 \int_0^t e^{\lambda_1 s - \lambda_h(t-s)} ds \leq c_5 e^{-\varepsilon t} \int_0^t e^{(\lambda_1 + \varepsilon)s} ds \leq c_6 e^{-\varepsilon t}. \quad (\text{A.36})$$

Thus by (A.33) and (A.36), we get $\sum_{n=1}^\infty \mathbb{P}_{\cdot, \delta_x} \left[\left(e^{\lambda_1 n \sigma} \langle g, Z_{n\sigma} \rangle \right)^2 \right] < \infty$. Consequently, (A.32) follows by Borel-Cantelli lemma.

Acknowledgement. We thank Zenghu Li for helpful discussions on Kuznetsov measure for superprocesses.
